This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

**Usage guidelines**

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

**About Google Book Search**

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

# Mining and Metallurgy

## INDEX TO VOLUME 3—NUMBERS 181-192

### JANUARY-DECEMBER, 1922

NOTE

An asterisk before the page number indicates an illustrated article; E, an editorial; B.M. means Bureau of Mines, and abs. stands for abstract. Names without added information indicate notes in the Personal column. Month of publication is given, followed by page number; for example, Feb. 11 means page 11 of the February number.

A

Page

Abandoned shafts and pits, precautions in entering ..... abs. B.M. Apr. 31
Absenteeism of mine workers ..... * May 11
Accidents at coal mines. Apr. 38, June 24, July 19
Anaconda Copper Mining Co. ..... Sept. 33
cost factor in coal mining ..... July 19
hoisting, three classes ..... abs. Feb. 50
mines, B.M. recommendations in 1915. E Oct. 3
prevention ..... Sept. 57
results ..... May 32
rates for mineral industries ..... Apr. 29
statistics, Franklin Mine, N. J. Zinc Co. Sept. 57
three classes ..... Sept. 33
Accountant's part in economic situation .. Sept. 40
Acetylene, precipitant for cyanide solutions ..... Aug. 30
Activity or prosperity ..... E July 1
Adams, C. A., speech at presentation of medal to Marconi ..... Aug. 7
Adiassevich, A. V., biography ..... June 46
Adkinson, H. M. ..... July 45, photo 48
Advancement of Science, American Association ..... Feb. 70, Mar. 68
Africa, South, associated societies ..... Jan. 16
honors A. S. Dwight ..... Dec. 5
Agitation, copper treated by ..... Sept. 16
Ahles, R. L., biography ..... Jan. 26
Air compressors, vertical ..... Dec. 53
Akerman, A. R., biography ..... Aug. 42
Alabama, University, research fellowships June 35
Alaska, coal mines ..... May 46
investigation by Dept. of Commerce .... Apr. 30
Alchemistic symbols for common metals. * Nov. 50
Alderson, G. E ..... Feb. 67
Aldridge, W. H., photo ..... Mar. 21
Allen, C. A., Inventory of Results of Accident Prevention ..... May 32
Allen, C. A. and Watts, A. C., Fighting a Mine Fire with its Own Gases, abs. B.M., Apr. 31
Allen, G. L ..... July 45
Allison, A. C., Parker, W. L., and Jones, G. W., Determination of Oxides of Nitrogen ..... abs. B.M., Jan. 47
Alloys, aluminum ..... Mar. 69
antimony, testing ..... June 18
bearing metal ..... abs. Feb. 63
boron in steel ..... Oct. 20
conference on non-ferrous ..... July 52
copper, methods for analysis ..... June 18
inhomogeneities in ..... Nov. 72
iron-carbon, stable equilibrium .. abs. * Aug. 38
zinc-aluminum, oxidation and swelling ..... abs. Aug. 39
zinc-base, binary ..... Feb. 64
Altio, K. F ..... June 46
Aluminum, and its alloys ..... Mar. 69
castings, numbering ..... Sept. 24
production, 1900–1920 ..... Feb. 10
Ambrose, A. W ..... Oct. 37
American Brass Co. controlled by Anaconda Copper Mining Co. ..... Mar. 5
American Engineering Council (See Federated American Engineering Societies).
American Institute of Electrical Engineers (See Electrical).
American Institute of Mining and Metallurgical Engineers (See Institute).
American Society of Mechanical Engineers (See Mechanical).
American Society of Civil Engineers (See Civil).
American Mining Congress officers ..... Nov. 49
American Relief Administration, engineers work in Russia ..... Nov. 35
American Society for Testing Materials (See Testing).
American Wood Pipe Co., acid-proof mine pipe ..... June 60
America's present duty to Europe ..... E Nov. 5
resolution. N. Y. Section, A. I. M. E. .. Nov. 63
Ammonia, solvent of oxidised copper .... Sept. 17
Ampere, brief note on centenary ..... Jan. 27
Anaconda Copper Mining Co., accidents and fatalities ..... Sept. 33
Bureau of Safety ..... abs. Feb. 38
electric signal installations for hoisting. abs. Feb. 43
handling ore, Butte District ..... abs. Feb. 45

Page

Anaconda Copper Mining Co.—continued
haulage systems, Butte mines .. abs. Feb. 43, 46
mine contracts ..... abs. Feb. 54
owner of American Brass Co. ..... Mar. 5
power distributing system ..... abs. Feb. 42
sampling ..... * Feb. 31, abs. Feb. 52
stope cost records ..... abs. Feb. 54
underground fire prevention ..... abs. * Feb. 37
ventilation of Butte mines ..... abs. * Feb. 40
wire rope and safety in hoisting .... abs. Feb. 48
Analysis, A. S. T. M. methods for lead, tin, antimony and copper alloys ..... June 18
coke ..... July 20
spectrum in industrial laboratory .. abs. Feb. 62
Annapolis, graduates study metallurgy at Carnegie ..... Sept. 38
Anderson, J. K., photo ..... July 48
Andrews, C. W ..... July 45
Anthracite (see Coal).
Antimony alloys, methods for analysis ... June 18
Appleby, W. R ..... * Apr. 18
Argall, P., biography ..... May 36
Argentina, American engineering societies Aug. 45
Argonaut mine disaster ..... E Oct. 3
rescue work ..... * Nov. 27
Armstrong, L. K ..... Mar. 61
Arnold, E. C., biography ..... Feb. 68
Arnold, R., Foreign Oil Possibilities and Domestic Price Fixing ..... June 15
Arnold, R., Bryan, B., and Macready, G. A., Petroleum Resources of Venezuela ..... abs. July 34
Arnold, R., English, W. A., Canadian Oil Reserves ..... abs. July 40
Arsenical bearing metals ..... abs. Feb. 63
Arthur, J. E ..... July 45
Artillery cartridge cases, testing .. abs. * Apr. 33
Asbestos, filter cloth ..... Dec. 54
subject at section meeting ..... Feb. 75
Ashio copper mines, mining methods, abs. * Feb. 57
Ashmead, D. C., Can Anthracite Mines be Operated Profitably on More than One Shift? ..... abs. Feb. 58
Assessment work and size of claims, mining law ..... June 20
in West ..... Mar. 24
requires capital ..... July 25
Atcherson, R. W. H ..... Sept. 51
Atlee, J. W ..... Aug. 41
Atwater, R. M., Jr., Coal Industry is Sick May 26
Audit, the technical ..... June 17
Austin, L. S., Evolution of Mechanical Roasting in Silver-lead Smelting ..... Aug. 27
Austin, M. M., Schwartz, H. A., Payne, H. R., and Gorton, A. F., Conditions of Stable Equilibrium in Iron-carbon Alloys ..... abs. * Aug. 38
Australia, zinc and lead smelting ..... Sept. 23
Automatic substation demonstration .. * Feb. 86
Astec gold mine, Baldy, N. M., geology, methods and costs ..... abs. * Oct. 33

B

Bacon, R. F ..... June 46
Bain, E. C., Crystal Structure of Solid Solutions ..... abs. Feb. 61
Bain, H. F., addresses Boston Local Section May 43
Conservation vs. Control of Profits .. Aug. 23
Waste Involved in Preliminary Investigation of Mineral Deposits ..... Mar. 23
Ball, S. H., Licensing an Example of Unnecessary Laws ..... Feb. 35
Bancroft, W. D., Colloid Chemistry and Metallurgy ..... abs. Dec. 29
Barba, W. P., and Howe, H. M., Acid Open-hearth Process for Manufacture of Gun Steels and Fine Steels ..... abs. Jan. 32
Barbour, P. E ..... Apr. 39, Sept. 51
Appointment of Officers of Reserve Corps ..... E Sept. 6
Black Future of Patent Office ..... E Feb. 4
Code of Ethics for all Engineers ..... E Apr. 5
Columbia Mining Scholarship ..... E Feb. 3
Employment Service to Executives .. E Feb. 4
Exempting Those Who Don't Want to be Licensed ..... E June 3
Fact-finding Commission for Coal Industry ..... E Nov. 3
Federated Support of Mining Law Revision ..... E Oct. 4
Flushing of Culm and Mill Tailings into Mine Workings Patented ..... E Sept. 5
Four-months' Strike Cost Anthracite Miners Two Years' Savings ..... E Sept. 4
Handling the Industrial Problem .... E Nov. 4
Industrial Morale and Employees' Magazines ..... E Sept. 6
Legal and Academic Definitions of Engineering ..... E Mar. 3
Modern Galvanising in Disrepute .... E Oct. 5

Page

Barbour, P. E.—continued
Officers of the Institute ..... May 5
125th Meeting of Institute ..... Mar. 7
Our Greatest Investment ..... E June 4
Patent Office Relief Bill ... E Mar. 4, E Apr. 5
Responsibility for Argonaut Disaster .. E Oct. 3
Revision of the Mining Law ..... E Apr. 3
Topographic Appropriation Cut ..... E Mar. 4
Transactions Desired ..... Apr. 41
Yonkers Gold Mine Fake and Licensing E Sept. 5
Barron, G. D., photo ..... Mar. 22
Barstow, W. S., Coal and Public Utilities May 14
Baskerville, C., biography ..... Mar. 62
Bassett, W. H., photo ..... Mar. 22
Bassett, W. H., and Davis, C. H., Spectrum Analysis in an Industrial Laboratory ..... abs. Feb. 62
Batholith, British Columbia, and related ore deposits ..... abs. * Aug. 34
Bearing-metal, alloy ..... abs. Feb. 63
arsenical ..... abs. Feb. 63
Beck, E. L ..... May 35
Belgium, coal at Campine ..... * Aug. 13
Liége graduates meeting ..... Apr. 26, June 59
production of coal ..... Aug. 13
Bensel, J. A., biography ..... Aug. 42
Benton, L. B ..... May 35
Berkey, C. P ..... Sept. 51
Berrien, C. L., Stope Cost Records and Mine Contracts of Anaconda Copper Mining Co ..... Feb. 54
Berry, E. S., Present Value in Relation to Ore Reserves, Plant Capacity, and Grade of Ore ..... July 11
Best, W. N., biography ..... June 45
Betterton, J. O., Soluble Silica in Preparation of Zinc-sulfate Solution for Electrolysis ..... abs. Dec. 30
Billings, R. S., photo ..... July 48
Billips, L. A ..... Jan. 25
Bituminous (see Coal).
Blackdamp, Utah ..... abs. B.M. Feb. 79
Blackwelder, E., Petroleum Resources of China and Siberia ..... abs. July 41
Blades, E. O ..... Aug. 41
Blast furnace, and manufacture of pig iron, book review ..... Dec. 49
magnetic ore in ..... abs. Dec. 32
powdered coal for lead ..... Oct. 25
practice, present-day iron ..... Mar. 43
progress in France ..... Nov. 50
slag, disposal of ..... Sept. 24
Blasting, eliminating waste in ..... Sept. 24
Blauvelt, W. H ..... June 46
Coal Miners' Demands and Way to Solution ..... May 18
Blauvelt, W. S., Economic Causes of Waste which Increase the Cost of Fuel. Sept. 9
Blende roasting, autogenous, zinc ..... * Dec. 11
Block method of showing costs ..... E Nov. 5
Bloomfield, D., Industrial Morale and Employees' Magazines ..... * Sept. 25
Bloomfield, J. J., Katz, S. H., Tests of Hand Extinguishers on Zinc-dust Fires. abs. B.M. Sept. 58
Blower, propeller, screw-blade ..... * Aug. 52
Blue constituent in high-strength manganese bronze ..... May 31
Blue powder in zinc smelting ..... Apr. 13
Boardman, J. L., Anaconda Accidents and Fatalities ..... Sept. 33
Boardman, J. L., and Goodale, C. W., Bureau of Safety of Anaconda Copper Mining Co ..... abs. Feb. 38
Boeck, J. W. and Woyski, B., Gas Absorption and Oxidation of Non-ferrous Metals ..... abs. * May 29
Boeke, C. L ..... May 35
Boericke, W. F., Sampling and Estimating Zinc and Lead Orebodies in Wisconsin .. abs. Feb. 53
Boilers, gas burners in oil-field .. abs. B.M. Aug. 47
marine ..... * Jan. 53
Book notices ..... Jan. 50, Feb. 82, Mar. 76, Apr. 52, May 49, June 56, July 57, Aug. 49, Sept. 61, Oct. 44, Nov. 68, Dec. 49
Boron as steel alloy ..... Oct. 20
Boston Local Section, A. I. M. E. ..... Feb. 76, May 43, June 50, Nov. 64.
Bounty, silver producers not receiving ... June 36
Bouton, C. M., Rate of Reduction of Hematite to Magnetite by Methane ... abs. B.M. Dec. 46
Bouton, C. M., Freeman, H. B., and Colburn, C. L., Experiments in Underground Signalling with Radio Sets ..... abs. B.M. Dec. 46
Bowden, R. K ..... Oct. 37
Bowie, C P., Oil-camp Sanitation ..... abs. B.M. Jan. 47
Bowie-Gavin oil-cracking process ..... July 20

Western Air Dump Cars Starting to Remove Sacramento Hill for the Copper Queen Mining Co.

# You American Institute Engineers

Do not exalt the Steamshovel, as in October *Mining and Metallurgy*, and ignore its equally important handmaiden, the **air dump car.** Those great stripping shovels, installed by the Steel Corporation on the Mesaba Range, described in October, would be helpless without the **Western Air Dump Cars** which the Steel Corporation also has installed, *to lower production costs.*

Steamshovel Mining is a Dump Car proposition. Your problem is not excavation but the economic removal of the material—a big problem where the time of your steamshovel is worth from $1.00 to $2.00 a minute.

The U. S. Steel Corporation made exhaustive tests to determine the relative efficiency of various makes of air dump cars for stripping.

WESTERN *Air Dump Cars were installed.*

The Copper Queen Company at Bisbee wanted the most efficient air dump car made, for hauling away Sacramento Hill.

WESTERN *Air Dump Cars were installed.*

The United Verde Copper Company, on going to a steamshovel basis, at Jerome, demanded the most efficient air dump car obtainable.

WESTERN *Air Dump Cars were installed.*

The reason is that Western Air Dump Cars, because of their superior mechanical design, dumping power and quality of construction, LOWER PRODUCTION COSTS.

Steamshovel mining is a HAULAGE proposition and haulage has been our specialty for more than 40 years. Our own engineers, working with you, may help develop a layout and installation that will lower your production costs. Give them a chance to try.

Write today for our Dump Car Catalog, Y-51.

## EDITORIAL

### Waste in Industry

I THINK that a rather unfortunate thing about the report of the committee of the Federated American Engineering Societies was its title. "Waste" is commonly associated with the ideas of profligacy or carelessness in the use of something that has been produced. If, for example, the manager of this magazine bought paper in sheets of such size that about one-third of the weight had to be sacrificed in trimming down to dimensions, that would be recognized instantly and correctly as waste, and the management would be reprehensible. If, however, the management, without being either profligate or careless, were failing to produce the magazine as economically as might be done by one of greater intelligence and ability, no accusation could be brought against it except that of unintelligence and incompetence. In industry, labor is guilty of waste when it insists that two men be put upon a job that one can easily do. I doubt if management is chargeable with so much actual waste as is implied, though it is true that it is often inefficient, and, moreover, that many of our industries function badly. I conjecture that the committee probably holds just these views, and it is likely that it employed the term "waste" simply as a convenient expression. I grant that it is not easy to find a better one.

It is no part of my thought to discuss the division of responsibility between management and labor, which I do not think can soundly be expressed numerically in such a way as the committee has essayed. I am not going to raise any issue upon this point, for I believe that experience has amply proved that neither labor nor politics, nor both together, can effectively direct industry; and the whole responsibility must be shouldered by those who have the ability to manage, asking of labor only that it will not stand in the way. Let management, therefore, earnestly study the committee's report and try to profit from it. There is much in it that is suggestive and constructive.

Digitized by Google

Lest the report be accepted as a gospel upon the evils of management as heretofore exhibited in the United States, let me, however, draw attention to two things about it that have struck me especially. One is the danger that readers of the report may consider that the derelictions of management are measured against a scale of superior intelligence, *i.e.*, against what engineers and experts think ought to be achieved, not what the several industries known how to do. This is not what the committee intended to convey, inasmuch as a careful reading of its report shows that the standard of measurement was the best actual performance in each industry. The other thing that struck me especially is that the industries selected for study and report, *viz.* building, men's clothing manufacturing, shoe manufacturing, printing, metal manufacturing, and textile manufacturing, comprise several that are notoriously badly organized. Some of the great industries like metal mining, metallurgy, and chemical manufacturing were not included in the survey. I conjecture that if such affairs as those of the U. S. Steel Corporation and the Anaconda Copper Mining Co. had come within the scope of the committee's examination, it would have had a different story to tell. Organization in the only practicable way is, however, one of the things whereof many persons complain. The theoretical, or I might better say the hypothetical, organization of industry has not worked at all, as Lenine and his collaborators in Russia have recently testified.

It seems to me that the committee has been somewhat querulous and has fallen short of a broad economic view. For this reason I hesitate to accept some of its conclusions, or if I do so it is with reserve. One of the greatest faults that it finds with our industries is the irregular employment that they afford, and their overbuilding and overmanning. These evils—for evils they are indeed—are closely associated with business cycles, a subject that I discussed last month. The undulations may be tempered by greater transparency in industry—I am using this expression in the economic sense—but heretofore the management of industry has not known how to accomplish this. It cannot fairly be blamed for what it has not known how to do. It is working now actively in that direction and we hope that something useful will be achieved, but we do not know yet that it will be, or can be. I have no doubt that the committee had a full understanding of these limitations, and I am drawing attention to this subject more in the way of warning against misinterpretation of the committee than of criticizing it.

Overbuilding is, in a way, a consequence of obscurity. There comes a sharp upturn in industry, increased profits and the temptation to provide new plant for the purpose of participating in the profits. Owing to imperfect knowledge of conditions, everything is always exaggerated and overdone. With the inevitable turn of the tide downward the industry is left with an expanded administration and an enlarged personnel, with the consequences that the latter can not obtain full annual employment and the cost per unit of production is enhanced by that and other factors. The bituminous coal-mining industry is the classic example of such a deplorable situation.

The committee found similar conditions prevailing in boot and shoe manufacturing, in the making of men's clothing and in other industries. Recent investigations of my own lead me to believe that not only is the committee right as to this, but also that in general American manufacturing industry is greatly overbuilt at the present time. This is largely a consequence of the war. It is partly a consequence of natural overenthusiasm on the part of the American business man. But it is partly a result of labor unionism. I am not sure whether the last has heretofore been brought out.

Labor is characteristically immobile, *i.e.*, it tends to cling to its habitat. For example, by chance the manufacture of shoes was started at Lynn, and of copper goods at Waterbury early in the history of this country. The respective industries continued in those places for no particular reason other than the development of populations skilled in the art, who grew up there and were indisposed to move away. In the course of time, however, the exactions of labor unions became so onerous that some shoe manufacturers were forced away from Lynn and Haverhill, and gradually the industry became so spread out that it attained the chronic condition of being overbuilt. In the same way printing was extended from the cities to the near-by country towns. During the last ten years the manufacture of women's garments, employing about 50,000 workers in the vicinity of New York, has been diverted from large, organized factories to a myriad of small shops dispersed over a large area, urban and suburban. In the consideration of efficiency of industry, attention ought to be given to major questions like these.

It is but recently that there has been begun the study of industrial and economic conditions by minds capable of seeing things broadly and understandingly. The professors of economics who have ventured into this field see things commonly in only an academic way, while other students who are unacademic are apt to be unscientific. There have been, for example, pretentious studies of the eight-hour day, but among them there has not been anything adequate. What scale of living the American worker can obtain at the present time by a universal eight-hour day is absolutely unknown, although of course we know what a part of the workers can achieve at the expense of the others, especially when they are assisted by the mechanicalization of industry resulting from the brains of engineers. Reflections of this nature give rise to little thoughts in my mind that perhaps the committee in minutely examining individual trees, and even their leaves, did not always get a true perspective of the whole forest.

W. R. Ingalls.

# Marshal Foch Made Honorary Member of Engineering Societies

MARSHAL Foch has been made an honorary member of the four national American societies of civil, mining and metallurgical, mechanical, and electrical engineers. The governing bodies of these societies, aggregating 45,000 members, conferred this signal honor in expression of the appreciation of American engineers for the unmatched services of this master of engineering principles.

At Engineering Societies Building, in New York City, on Tuesday afternoon, Dec. 13, the presidents of the four societies presented one beautifully engrossed certificate of honorary membership in the four societies. The auditorium was filled so that not even standing room was left, more than a half hour before the ceremonies began, and the main entrance on the street had to be closed. J. Vipond Davies, president of the United Engineering Society, made the opening address. Col. William Barclay Parsons, who was commander of the first engineer regiment to go abroad, addressed Marshal Foch in French. Colonel Parsons said:

The art of engineering was defined a long time ago as "the art of directing the great sources of power in nature for the use and convenience of man." No better definition can be found today. Of all the sources of power in nature, the greatest, the most valuable, and at the same time the most difficult to direct, is the energy of man himself. He who can direct human energy and turn it to the service of mankind is a great engineer.

You, Marshal, have directed a greater mass of human energy than any other man has ever done. And you have successfully directed this mass for the highest uses of mankind, in that you by its aid have preserved for him one of the most precious of human possessions—liberty—liberty not only for your own illustrious country, but for all the nations of the world.

The four national engineering societies of the United States now desire to make record of their appreciation of this fact and to convey to you an expression of their most profound admiration for the great leader of men by conferring on you honorary membership in all the societies, the highest honor in their gift and one hitherto never conferred on a single individual.

Four thousand members of these societies were enrolled in the armed service of the United States, the greater part of whom had the glorious distinction to serve the common cause in France under your orders. They heard the voice and they saw the hand of the master as he led them through battle to victory. Now we desire that you will still continue to lead us, but in peace, by permitting us to inscribe your name at the head of our roll of honor, where it will be, as your deeds have been, an example to us to do better work, and where it will remain forever a noble inspiration for all future generations.

Marshal, in the name of those members of the societies who served under your orders and particularly in the name of those who fell on the field of honor in France, I salute you.

He was followed by George S. Webster, president of the American Society of Civil Engineers, who presented to Marshal Foch the certificate conferring upon him honorary membership in the four national societies.

Marshal Foch responded in French and again, as when he made his first appearance, was received with the greatest applause and enthusiasm. He said:

It was due largely to engineering and the engineering industry that the war was brought to a successful conclusion. To the engineering profession also we are indebted for many great lessons which will be vital to mankind in the future.

The armies could not have done a great deal without the effort of the engineer. Success was made possible to a great extent by the industry of the people at home, but when it became a question of decision, when the decisive moments arrived, the engineer stood out as an essential factor in complete triumph.

What would have become of the armies without the technical training, without the professional knowledge which you have exercised for the Allies and which enabled us to lead our armies in the field, to feed them, to protect them and to facilitate their advance quickly and decisively?

It is for these reasons that I am pleased to meet you here today, to receive from you so splendid a welcome and to express my gratitude and the gratitude of France, as well as the recognition of my countrymen for the tremendous sacrifices made by you and the men of your calling.

I am grateful to you for including me in your ranks as a member of the four great engineering societies of the United States. Believe me, this honor which you have conferred upon me I indeed appreciate and I shall cherish this event with the happiest memories.

Charles P. Perin then made a short address in French and presented each of the presidents of the four national societies with replicas of medals struck in commemoration of the Marshal's visit to the United States.

The arrangements of this elaborate function were in the hands of Charles F. Rand and, inasmuch as every detail had been foreseen, the arrangements worked perfectly and the function was an inspiring success.

Marshal Foch presented each society with an autographed photograph of himself (like the frontispiece of this number) and, in addition, an autographed French edition of his "Principles of War" for the Engineering Societies Library.

The Marshal's visit to this country as guest of the American Legion has revived and enhanced our appreciation of his incomparable service and of the victories of the soldiers of the united nations typified by the American Legion.

CERTIFICATE PRESENTED TO MARSHAL FOCH BY THE FOUR NATIONAL ENGINEERING SOCIETIES

Digitized by Google

The fundamentals of engineering achievement are coöperation and coördination. It was the ability of Foch to supplement his military genius with the effective coöperation of the commanders of the armies of five nations and the coördination of their operations that won the great victory.

Late in March, 1918, with the British Fifth Army shattered and the situation of the Allies decidedly precarious, Haig telegraphed to Lloyd George to come to France and informed him that in his opinion a single commandership should be established. Lord Milner was sent. Poincaré and Clemenceau were informed. These three met, with their principal generals, at Doullens on March 25, 1918; with Clemenceau, was Foch. After a half-hour's private conference between Milner and the British generals, all assembled. Clemenceau reviewed the military situation very briefly, questioning the commanders, and then presented Foch, giving a short statement of his fitness. Milner asked for a moment in private with Clemenceau; they retired to a corner of the room. Without preamble, Milner said: "The British generals accept the commandership of Foch." Clemenceau responded: "Is that from your Government?" "The British Government has guaranteed that it will ratify whatever we decide. Are you in accord?" "We agree. Now we must have a suitable form of announcement. We will see Foch." After a half-minute's reflection, Foch quickly wrote: "By decision of the Governments of Great Britain and France, General Foch is charged with coördinating on the west front the operations of the French and British armies whose commanders-in-chief, Marshal Haig and General Petain, will be given all the directions required for the establishment of such coördination."

Seven months and a half later, Foch was chief figure in another historic conference. Near Rethondes, in the forest of Compiegne, he received the German plenipotentiaries. The interviews occurred in the Marshal's train, which, built for the Liége Exposition, has become historic. A witness has described the first interview. Foch arose majestically and made a slight salute to the plenipotentiaries.

"Gentlemen," he said, "introduce yourselves. You have before you Generalissimo Foch; here is my chief of staff. Now show your credentials. . . . Good, your papers are in order. What do you wish?"

"We have come to discuss the armistice."

"I do not understand. Discuss? You mean to receive our armistice conditions."

As Erzberger attempted to engage in a discussion, he continued: "It is not a time for discussions. It is a question of taking or leaving. Otherwise the war will continue. You have forty-eight hours to make your reply. Gentlemen, you may withdraw."

The outcome was the armistice, signed on Nov. 11, 1918.

The possibility of continuing on to Berlin was discussed repeatedly before the interview with the German plenipotentiaries, but Marshal Foch deemed it wiser to see if the Germans would accept the conditions of the Allies. "These conditions are just as hard" he said, "as if we were in Berlin. The opportunity has arrived. It must be seized. Merely to obtain—perhaps—a satisfaction which would bring no further real advantage, the Marshal does not wish to risk so many more human lives, nor to exact too many sacrifices from troops which have suffered. Yes, we might go further, we might impose upon Germany a new Sedan, but it would be necessary to sacrifice thousands of men, and that I ought not to do."

Chronologically arranged, the events in Marshal Foch's career to the beginning of the war are as follows:

| | |
|---|---|
| 1871 | Student, École Polytechnique |
| 1873 | Student, École d'Application d'artillerie |
| 1874 | Lieutenant assigned 24th Regiment artillery at Tarbes |
| .... | 2 years student at École de cavalerie |
| 1878 | Captain, 10th Regiment artillery at Reunes |
| .... | In "Section Technique" of Ministry of War |
| 1885 | Chosen for École de Guerre |
| .... | On staff of division |
| 1891 | Major attached General Staff |
| .... | Commander of 3rd battery horse artillery |
| 1894 | Back to General Staff |
| 1895 (Oct. 31) | Associate professor of military history, strategy and applied tactics at École Supérieure de guerre, or Staff College. |
| 1896 | Lieutenant Colonel. Full professor. |
| .... | Lectures at École de guerre issued in two books: "The Conduct of War" "The Principles of War" |
| 1900 | Went to 29th Regiment artillery |
| 1903 | Colonel, 35th Artillery at Vannes |
| 1905 | Chief of Staff, 5th Army Corps at Orleans |
| 1907 | Brigadier General, General Staff |
| 1907 | Director, École de guerre |
| 1909 | Gave course in Higher Strategy Originated School for Marshals |
| 1911 | General of 13th Division |
| 1912 | Command 8th Army Corps |
| 1913 | Command 20th Corps at Nancy at outbreak of war |

By official decree Aug. 6, 1918, Foch was made a Marshal of France. This military rank, abolished at the overthrow of the Empire, had been revived by a decree, Dec. 24, 1916. His baton bears the name of Ferdinand Foch, engraved in gold letters, with the inscription: "Terror belli decus pacis."

Ferdinand Foch studied engineering in École Polytechnique and École d'Application d'artillerie. He served on the technical section of the Ministry of War early in life, and in later years was a full professor in École de Guerre.

No man can attain eminence as a commander of modern armies without mastery of the principles and practices of several branches of engineering. Ferdinand Foch was not only trained in the applications of engineering to military purposes, but also taught some of these branches in France's notable war schools and practiced them in the field.

## Building-trade Union Practices in New York

SOME of the practices among the labor unions in the building trade in New York that were brought out in evidence before the Lockwood Committee in December, 1921, are interesting.

Christian G. Norman, chairman of the board of governors of the Building Trades Employers Association, stated that for anybody to secure a license to run an electric hoister it is necessary first to pass an examination as a steam engineer at police headquarters.

The practices of the Plasterers' Union are particularly ingenious. It is required that models be destroyed upon completion of any job, although they are purchased from the union by the contractor. The president of the union explains that "it would throw our modelers out of work if these models were passed around too freely."

During the construction of the Ambassador Hotel, the union caused part of a ceiling to be torn down because "certain union regulations had not been fulfilled."

Whenever more than three men are required for a plastering job, a fourth must go with them to act as foreman.

The vice-president of this union, which comprises about 25,000 members, said, "The meanest thing I know of is for a workman to commence work before 9 o'clock and to keep on after the whistle blows at five. That is meaner than picking a man's pocket."

The Electrical Workers' Union has derived a huge income by restricting its membership to 3800 (about one-fourth of the electricians in the city) and issuing working permits at $2.50 per week to non-union workers.

Reverting to the Plasterers' Union, one day recently 21 men were fined $5 each for an offence known in the trade as "browning on green scratch coat." The fines in such cases go into the treasury of the union, but the owner or builder who had the bad job wished on him has to pay for having it rectified.

"When a job is botched and the men fined on account of it, wouldn't it be a good idea for the union to pay for it out of the fines?" asked the investigator.

"Well, I never thought of that," replied the president of the union.

The requirement that every three-man job should have a foreman was not apparently a fixture, for in one case a man who was building an apartment house was fined $75 for refusing to employ a foreman on a job that took only two men.

It was brought out with the aid of records of the union that a squad of plasterers on a certain job was held until 5.10 p.m. one day, while the employer was occupied in paying them off. For this offence the employer was required to pay $2.38 per man, *viz.*, one-fourth day wage for the 10-minute delay. Another employer was fined $1000 for paying his men for over time on the hour and half-hour bases instead of the quarter-day, which latter the union prescribes as the minimum.

If anybody wants to have a room redecorated and there are cracks in the plastering, the painter can not fill the cracks, no matter how small they are. A plasterer must come for that purpose.

"Soldiering" on the job has been a regular principle, as was testified by numerous witnesses. There were, however, ways of curing this. One contractor testified that in building an apartment house 22 plasterers finished only 11 rooms in three days. It was highly desirable to complete the job by the end of the week. There remained 2½ days and 48 rooms to do. The contractor bet the foreman $100 that it could not be done. It was done.

It is not only the employers that the leaders of the union have soaked. The members of the union themselves have been mulcted from time to time. The minutes of the executive committee of the Plasterers' Union showed that it was customary to fine plasterers for working a few moments over time and to discipline foremen for helping out men when they were in difficulties in their work. One foreman was expelled from the union for a year for showing an inexperienced plasterer how to handle his tools more effectively. It was brought out that there is a rule in the union preventing any man from "rushing on the job," *i.e.*, working faster than his colleagues. The opinion was expressed by one union leader that "a laborer who rushes a job is guilty of a crime almost equal to murder."

Nine workmen of Italian, German and Hebrew extraction were fined $19 each for working on St. Patrick's Day, 1920. St. Patrick's Day is not a legal holiday in New York.

A certain member of the union was fined $115 by the executive committee for making out an affidavit in a suit for an injunction against the union.

These are not excerpts from a humorous book, but are from the records of hearings by a legislative committee. In the building trade of New York City about 100,000 to 120,000 men are employed.

## American Petroleum Institute Elections

THE directors of the American Petroleum Institute have just elected the following officers: Thomas A. O'Donnell, president; R. D. Benson, Henry L. Doherty, and J. W. Van Dyke, vice-presidents; H. F. Sinclair, treasurer; R. L. Welch, general secretary and counsel; W. R. Boyd, Jr., assistant secretary and counsel; C. C. Smith, assistant treasurer.

The following new directors of the Institute have been elected: B. B. Brooks, Casper, Wyo.; J. D. Collett, Fort Worth, Tex.; George N. Moore, Chicago, Ill.; E. T. Wilson, Denver, Colo.; W. M. Welch, Tulsa, Okla.; Sheldon Clark, Chicago, Ill.; T. J. Gay, Little Rock, Ark.; E. C. Lufkin, and E. B. Reeser, New York.

# Caving Systems of Mining

By J. PARKE CHANNING
Vice President, Miami Copper Company

THE caving system of mining is that method of removing the ore from an underground body in which the top is first attacked and mined out and the capping, or roof, as the case may be, is allowed to fall in or "cave" and fill the space formerly occupied by the mined ore. It is applicable, generally, to large orebodies where the ore is relatively soft. We may say, within moderate limits, that when ore is removed the surrounding ground either caves in or remains open. For example, in mines like the Lake Superior amygdaloid copper mines, when the lode is removed there is left a void which remains open for many years; on the contrary, mining a Lake Superior soft hematite ore, however carefully it may be done, always produces a caving of the surrounding rocks. We may say, with propriety, therefore, that the caving system is applicable to that type of ore deposit in which the surrounding rock readily caves.

Another factor which governs the use of the caving system is the value of the ore itself. Admittedly, any form of caving will not extract 100 per cent. of the ore, and in the case of a very rich orebody it is often desirable to get out every pound of the ore with as little dilution as possible. Under these conditions, some other method of mining, such as that by square sets and filling, is indicated and should be followed. We may say, however, that, looking at it broadly, in the United States the caving system of mining is generally used for the removal of soft hematite and for the so-called "porphyry" coppers. In both cases this method is used where open-pit mining is not possible.

## Three Caving Methods

Caving systems of mining may be divided into three general classes; top slicing, sub-drift caving, and block caving. In top slicing, successive layers, usually about 10 ft. in thickness, are taken, beginning at the top of the ore and so on successively down. In sub-drift caving, the ore is taken in thicker slices; say, for example, from 14 ft. to 22 ft. thick, of which the lower 8 ft. is taken out with timber and the upper 6 to 14 ft. is pulled down and drawn on the retreat. The block caving system is one in which the slices are anywhere from 35 to 100 ft. in thickness and in which the ore, after suitably breaking up, is drawn out through a multiplicity of chutes in a series of drifts driven at the bottom of the slice.

In attacking a new orebody whose outline has been sufficiently determined, in the two cases first mentioned, it is frequently the practice to establish a level near the top of the orebody, but below the deepest irregularity of the capping, and mine out the first slice by square sets. This is done with a two-fold purpose, not only to give enough reach to the capping so that it may break and settle down, but also to establish a flat surface from which the slicing or sub-drift caving below may proceed in a regular manner. Great care must be taken in this preliminary operation, so that a cave may not occur with a sudden rush of air, with its resultant damage. This method is not always used, but has been found desirable and necessary in several of the Lake Superior hematite mines.

## Caving Introduced from Lancashire

It is well to consider first the sub-drift caving system, as this was the first method introduced into the United States. In 1881 or 1882, George W. Wallace was in charge of the Cleveland Hematite mine near Ishpeming, Mich. The orebody was a soft hematite which was being mined with square sets. There came to the mine two miners from Dalton-in-Furness, Lancashire, England, who were expert in what was known as the caving method and who explained it to Captain Wallace. He realized its good points and introduced it into the Cleveland Hematite, or old Nelson mine, as it was frequently called. I am not able to say whether the method used there was sub-drift caving or top slicing, but I am inclined to think that it was sub-drift caving. Captain Wallace wrote a description of the method about 1910, but it was never published and the manuscript was lost when he moved to the west.

The first time I saw the sub-drift caving system was at the Brotherton mine at Wakefield, Gogebic County, Mich., in 1886. John Pengilly was in charge of the mine, having been sent there by D. H. Bacon, who was at that time general manager of the Cleveland Iron Mining Co., and under whom Captain Wallace was mining captain at the Cleveland Hematite. The Brotherton hematite was a rather soft ore and the orebody was of somewhat irregular shape, varying in width from 20 to 40 ft. and dipping probably at an average angle of 45°, though at times the irregular foot wall was steep and at other times nearly vertical. The main levels were about 60 ft. apart and each lift was mined out in four successive layers of 15 ft. each. Raises were put up 50 ft. apart along the strike, and these were connected with sub-drifts, leaving in each case a 6- to 7-ft. back. Therefore, when a level

Digitized by Google

was opened, these successive layers of 15 ft. were opened, with drifts along their bottom.

Stoping or mining was started at the far end of the top lift, gradually drawing back toward the shaft crosscut, timber being used for the bottom 8 ft. and the top 7 ft. being drawn or caved as retreating was continued toward the shaft. A description of this may be found in an article written by myself.[1]

It is interesting to note that at about the same time Guy R. Johnson adopted a very similar system at the mines of the Longdale Iron Co. in Virginia.[2] Probably very soon after this a similar method was used in mining the orebodies in Lowmoor, Va., as described by W. S. Hungerford.[3]

I think the first time that we on Lake Superior realized that this work was being done in Virginia was when the late Guy R. Johnson, Sr., visited the Menominee Range in 1887–88, to examine the Chapin mine, and told us what he was doing. It shows how frequently the same problem is solved in a similar manner in different parts of the world. Since that time the sub-drift caving method has been in continuous use throughout the United States in various classes of mines and is today a good standard method. The thickness of the slice removed depends entirely on circumstances. If reduced to the mere height of the regular drifts, the method is the top-slice system, and when the thickness becomes 35 or 40 ft. or over, the method merges into the block caving system.

### Factor of Success of Sub-drift Caving

The success of the sub-drift system depends very largely on the building up of a "mat" of crushed timber between the ore and the broken capping or "gob." Even at the best this "mat" is never perfect and when the ore from above the timbers of the extraction drift and below the "mat" is drawn out, waste material invariably trickles down through it and dilutes the ore. At times rushes of the "gob" come and some of the ore is lost. In hematite mining, where very frequently the "gob" is a low-grade iron ore, this dilution does not amount to much, but often in the mining of "porphyry" ores, where the ore may run 2 per cent. in copper and the "gob" only 0.2 per cent., this dilution and loss is of importance. It is evident, however, that the thicker the slice in the sub-drift method, the less ore has to be breasted out or actually mined, and more ore is cheaply won by caving the upper part. Only the results of careful experiments and calculations can show the proper mean. There are many modifications of the sub-drift caving system and these are well described in numerous articles in the Transactions of the A. I. M. E.

In the top-slice system, haulage levels are put at any convenient distance apart, usually 100 ft. vertically. The haulage drifts themselves are sufficiently numerous and are so spaced that raises from them can reach the top of the orebody at points not more than 50 ft. apart from one another, the object being to avoid too much tramming to these raises in the slices. The usual thickness of one of these top slices is 10 ft., this being the distance from the bottom of the post to the top of the lagging, though sometimes the height may be only 8 ft. and at others it may be as high as 12 feet.

### Advantages and Disadvantages of Top Slicing

In taking out this top slice, various plans are used, dependent on the area of the orebody. Frequently a system similar to the long-wall retreating method of coal mining is used and a long face, the full width of one dimension of the orebody, is kept constantly open. The ore is removed in a drift along this face, perhaps two sets wide, then the further drift timber is blasted in and a new one driven back of the one left opened. This method, however, is often difficult to maintain, and a successful modification of it has been described by E. G. Dean.[4] In this case the slice is divided into 250-ft. squares with a central supply raise to each square and the usual number of raises down which the ore is dumped.

In any method of this kind, hand-tramming is necessary, to transfer the ore from the place where it is broken to the raise; this is done either by direct shoveling, by wheel barrows, or by small cars of one-ton capacity. Endless belts and scrapers have been tried, but without success. Great care must be taken, in this method of mining, to insure ventilation, as open drifts are not as numerous as in the sub-drift method. Good ventilation can be maintained, however, by a careful system of plenum and suction drifts which are not interconnected.

An interesting modification of the top-slicing method is that of making the floor of the slice inclined. This obviates to a large extent the necessity for shoveling and hand-tramming. Its use in the Coronado mine in Arizona is described by W. G. Scott,[5] but it is well to note that in the Coronado mine the orebody is relatively long and narrow and it is questionable whether this method can be successfully employed in a large orebody where it might be necessary to divide the slicing area into 250-ft. squares.

The advantage of the top-slicing system is that one has a practical control over the mining of the ore. It is in reality all breast stoped with, of course, an increase in cost as compared with the sub-drift system, but with the advantage that nearly all the ore is removed and the admixture of waste is reduced to a minimum. In case of any unexpected caving, in which a block of ore is temporarily lost, its position can be

Digitized by Google

accurately determined and a large part of it may be taken out on the next slice, either by square-setting or by drawing. In this connection, it will be desirable for the student to read the paper on Methods of Iron Mining in Northern Minnesota, by F. W. Denton.[6] On page 383 he refers to the Genoa mine, which, in the year 1897, mined about 300,000 tons by the top-slice method at a total cost of 41 cents a ton including all underground and surface expense, taxes, etc. This, I believe, is the record for underground mining on Lake Superior. I have not any unit costs on the Mesabi Range for that time but I do know that the cost of timber and planking was extremely low because at that time the pine in the district was being cut and marketed.

It is interesting to note the comparison Mr. Denton gives between top slicing and sub-drift caving, where he says, "Ore by such a method (sub-drifting) is, of course, much more cheaply broken than that which is sliced or broken out, but it is a question of both gain and loss."

### Development of Block Caving System

Block caving has resulted from a gradual development of some extremely crude methods of taking out pillars left from a room-and-pillar system of mining and from modifications of the sub-drift system. In the early days on the Gogebic Range, it was customary to mine the ore with square sets made of round timber, the rule being a three-set room and a three-set pillar. This made the room considerably wider than the pillar, equal to the thickness of one post and two sets of lagging. The room was carried up as far as was safe, perhaps leaving one or two sets between the back of the room and the floor of the level above. Care was not always taken that rooms should be under rooms and pillars under pillars. For a rough guess, probably not over 40 per cent. of the ore was taken out in the rooms and 60 per cent. was left in the form of pillars and floors. Drifts were then driven through the middle of these pillars undercutting the ore and drawing out what would come. Probably not over half of the remaining ore was taken out before the waste came, so that the gross extraction would not exceed 70 per cent.

In other mines, when attempts were made to increase the thickness of the slices in the sub-drift method of mining, similar losses and dilution took place. I think we may say that *successful* block caving systems grew out of the development of the shrinkage-stope method of mining in some of the large orebodies. In some cases, the orebody was divided into sections 50 ft. wide running from one edge of the orebody to the other and a 25-ft. overhand stope was started in each section, the men standing on the broken ore in doing their work, the excess ore being drawn out from chutes. When it came to removing the pillars it was often found that these would not cave of their own volition, or if they did, the pieces were too large and could not be drawn out when the shrinkage ore was drawn. This led to making the thickness of the combined room and pillar less, at times as small as 25 ft., with a 10-ft. shrinkage stope and a 15-ft. pillar, or vice versa. These operated better, and finally it was discovered that it was not necessary to put up these shrinkage stopes at all. All that was necessary was to get in hand-tramming drifts sufficiently close to undercut the ore and let it drop down and then draw it out through a multiplicity of raises. In some cases this undercutting was boldly attempted without having gone through the shrinkage-stope method, and this is particularly exemplified in what is known as the Ohio method, which is described in several places in the A. I. M. E. Transactions and in the *Engineering and Mining Journal*. This Ohio method is particularly noted for its economy of raising, all the raises being approximately at an angle of 45° and running off from each other like the branches of a tree. In the Ohio system the blocks or layers drawn are about 35 ft. in thickness, and at the Ohio mine, which is a particularly low-grade mine, it was an eminently satisfactory method.

### Difficulties of Properly Drawing Caved Ore

As has been pointed out frequently by Henry S. Munroe, for many years professor of mining at the School of Mines, Columbia University, it is not particularly difficult to undercut an orebody and break it up. The great difficulty has always been in controlling the drawing of the ore so as to prevent piping or funneling, and an undue admixture of waste with the ore. A modification of the Ohio method, employed at the Ruth mine of the Nevada Consolidated Copper Co., is clearly explained by Walter S. Larsh.[7] It will be noted, in the drawing on page 300, that the ore is drawn so as to maintain a line of contact between the broken ore and the caved capping, approximating 40°. As he says at the bottom of page 301: "The critical part of the whole system is to draw the ore properly after it has been caved. The expectancy of each raise series is calculated from all available data, such as drill holes, raises or other workings, and charted.

The amount to be drawn from each finger is determined by the stope engineers from the charts and model and is given to the foreman and bosses each shift. The angle of the contact between ore and capping from the raise series completed to those being brought in is maintained between 30° and 40°."

At the Miami Copper mine, in Arizona, after having gone through the experience of narrow shrinkage stopes and pillars, a block-caving system has been developed in which the blocks drawn are 75 ft. high. The main haulage levels are 150 ft. apart, so that the ore above each haulage level is taken out in two layers or blocks.

[6] *Trans.* (1897) **27**, 344.

[7] *Trans.* (1918) **59**, 299.

Digitized by Google

From any particular haulage level the top of the ore to be drawn is 175 ft. above the floor of this haulage level. The first hand-tramming level is established 100 ft. above the haulage level, or 75 ft. below the top of the ore. Parallel hand-tramming drifts are then driven, varying from 18 to 25 ft. apart up to the boundary of the ore. Along each hand-tramming drift, are dump chutes 50 ft. apart, which are connected, by a system of vertical and inclined raises, with the drifts in the main haulage level. Along these hand-tramming drifts numerous short raises with chutes are put in and at a somewhat higher level than the hand-tramming level, so-called mining drifts are driven; each mining drift is untimbered and is halfway between the adjoining hand-tramming drifts. After these hand-tramming drifts and mining drifts are put in, holes are drilled in the sides of the mining drifts and those nearer the extremity of the orebody are blasted, thus undercutting the ore and causing it to settle down just above the hand-tramming drifts. The broken ore from the chutes of the hand-tramming drifts is then drawn, under the same supervision as at the Ruth, so as to establish a plane between the capping and the broken ore, which in this case more nearly approximates 60° than the 30° or 40° mentioned for the Ruth. The ore from these raises is trammed back by hand, dumped down the nearest chute, and eventually finds its way down the main haulage level. On the general retreat, before any particular section of the hand-tramming drift is abandoned, the ore immediately on top of it is mined out in a manner similar to that of the so-called "mining drifts;" in this way the ore is practically drawn down to within a short distance above the hand-tramming drifts. If capping comes from any particular chute before the time determined by the engineers, it is known that piping has taken place. This particular chute is then sealed off and the surrounding chutes are drawn, which usually breaks up the pipe. The sealed chute is reopened and the clean ore usually comes after a few cars of waste are removed.

### Advantages of Miami System

The advantage of this system is that with its multiplicity of chutes the drawing of the ore is under complete control and a minimum amount of ore is lost and a minimum amount of dilution takes place. The whole orebody is not drawn back from the boundary but is divided into panels 150 ft. wide, leaving corresponding pillars between, so that each panel as it is drawn back is served by either six or eight hand-tramming drifts. After these panels have been drawn back a certain distance, the intermediate panels are attacked, this method reducing the great pressure that would occur if an attempt were made to draw the whole face at one time.

After the 75-ft. upper block is either mined or retreated sufficiently, the next hand-tramming level 75 ft. below and 25 ft. above the haulage level is opened in a similar manner, although possibly the hand-tramming drifts may be at right angles to those in the upper block. The result is that after the two blocks 75 ft. in height have been drawn the ore is mined down to a point 25 ft. above the main haulage level. In the meantime, the haulage next level below is prepared, but before drawing out the top block on the level below it is desirable to remove the timbers from the upper haulage level so that they may not interfere with the drawing.

In comparing the above method of block caving with straight slicing in copper mining, it may be said that the profit per cubic foot of original orebody will be more than by straight top slicing. The recovery of copper will not be as great per cubic foot of original orebody as that by top slicing, but it is more than made up for by the decreased cost. In comparing a good block caving system with top slicing, I should be inclined to say that for copper ore running 2½ per cent. or over, probably it would be more desirable to use the top-slice method, but that when the ore runs 2 per cent. or under the block caving system would be the better. One advantage of the block caving system is that it requires only half as many miners as the top-slicing method, and, of course, requires very much less timber. If the drawing is conscientiously carried out, the results are entirely satisfactory and the loss by dilution is reduced to a minimum.

---

## French Metallurgy and the Great War

A CAREFULLY prepared volume entitled "Nos Usines Métallurgiques dévastées" was issued recently by the *Revue de Métallurgie*. It contains 270 pages, with 300 illustrations, and consists of monographs by French engineers on certain large metallurgical plants that were destroyed by the Germans.

The introduction, which gives various statistics, is by M. Léon Guillet, professor of metallurgy at two of the technical schools in Paris. Abstracts of this introduction, in English, Spanish and Italian, follow the original. M. Guillet says that at the time of the Armistice, 11,500 French works had been destroyed, about 319,269 private dwellings had been razed, and about 313,675 partly demolished. Large numbers of railways, roads, canals, bridges and viaducts also required complete relaying and reconstruction.

The object of the book is to place on record a detailed account of this devastation, and to show that much of it was not made necessary by military requirements, but was systematic and deliberate destruction; also, to tell of the progress already made in the work of reconstruction and to solicit consideration and encouragement for French industrial undertakings.

The book may be obtained from the *Revue de Métallurgie*, 5, Cité Pigalle, Paris (9e), France. The price is 25 francs; post paid (within certain postal limits, presumably), 26 francs.

# Dusting and Volatilization Losses During Melting of Cyanide Precipitate and Air Refining of Bullion

By GALEN H. CLEVENGER, FRED S. MULOCK and GEORGE W. HARRIS

United States Smelting, Refining & Mining Co., Boston, Mass.

THE losses of gold and silver occurring during the conversion of the precipitate, resulting from the cyanide process, into bullion may occur in two ways: first, there may be mechanical losses during the handling of the precipitate up to the time that it is charged into the melting furnace; and second, there may be losses after the precipitate reaches the melting furnace.

Much of the loss during the handling of the precipitate can be eliminated, and in fact, in modern plants this loss is known to be very small; particularly since preliminary acid treatment of the precipitate with the attendant extra operations has been abandoned in all but certain plants where gold predominates and this extra step is still deemed necessary.

The losses in the melting furnace are from dusting and volatilization; losses in the furnace bottom and linings; floor sweepings; and slag and matte. The gold and silver in the products which do not go out of the flue are readily recoverable by standard methods, and while there may be considerable gold and silver tied up at times, the ultimate loss with careful work should be small.

The losses resulting from volatilization and dusting in connection with the melting of the silver slime from copper refineries have been determined by standard methods, and the possible recovery definitely established through the installation and operation of electrostatic precipitation units. This subject has not been thoroughly investigated in connection with the melting of cyanide precipitate; at least, there are no published accounts of such tests. Experiments have been made in the past to determine melting losses by weighing and assaying the precipitate, but this method gives results which are uncertain on account of the difficulty of accurately sampling and assaying cyanide precipitate. Attempts to ascertain these losses by bubbling a measured sample of the gas through cyanide solution or other absorbent have likewise failed to give dependable results.

The tests herein described were made on the melting furnaces of the Compania de Real del Monte y Pachuca, in order to determine the approximate dusting and volatilization losses during the melting of the precipitate and the volatilization loss during air refining of the resulting Doré bullion.

Zinc-dust precipitation is employed at the Loreto and Guerrero mills of the company. The Loreto precipitate averages 75 to 78 per cent. silver and gold and the Guerrero precipitate 80 to 85 per cent. silver and gold. The melting furnaces are at the Loreto mill and the Guerrero precipitate is taken there in special locked steel containers, by motor truck. The precipitate from each mill is melted separately and the byproducts, so far as possible, are segregated. The precipitate as charged to the furnaces contains 30 to 35 per cent. moisture.

The melting equipment consists of two oil-fired reverberatory furnaces with firebrick bottoms and of conventional design. We have designated them throughout this article as the "small furnace," which has a hearth area of 25 sq. ft., and the "large furnace," which has a hearth area of 49 sq. ft. Each furnace is equipped with two oil burners which are fired with Mexican crude oil residuum.

The regular procedure in melting the precipitate is to preheat the furnace; then a charge of precipitate, roughly mixed with the minimum amount of flux, consisting of borax glass and finely ground bottle glass, is shoveled by hand from shallow charge cars through the work door at the burner end of the furnace. After the first charge has melted, additional charges are added until the desired amount of bullion has collected on the hearth. The furnace is then tapped and the bullion cast directly into molds carried on a special casting machine.

In cases where the bullion was air refined, the desired number of charges were melted and the slag was tapped from the top of the bullion, the last of it being skimmed with a rabble and pulled through the work door. After removal of the slag, air refining proceeded. It has not been the practice heretofore to air refine, since there was no advantage in doing this when outside refineries did the final refining, but now that the company is to have its own electrolytic refinery, it has become a matter of considerable importance to ascer-

Digitized by Google

tain to what extent this cyanide bullion is amenable to air refining. It is generally recognized by refiners that it is desirable to eliminate base metals so far as possible by furnace refining prior to electrolytic refining. The tests of which an account is herein given were made, therefore, not only to determine dusting and volatilization losses but also to determine the extent to which this cyanide bullion could be air-refined.

The low-pressure air employed in the earlier experiments was supplied by a small Buffalo Forge motor-driven fan, while in the later experiments a small Roots blower having a delivery opening of 3½-in. diameter was used. The low-pressure air was blown over the surface of the bath from a flattened nozzle inserted through an opening in the back of the furnace and directed towards the work door. The resulting molten oxides were drawn off by cutting down the breast at the bottom of the work door. This operation resembles cupellation as carried on in the English type of cupelling furnace. The high-pressure air from the mill compressors, in those tests in which it was used, was introduced through a length of ½-in. gas pipe inserted through the work door and immersed in the bath of molten metal. This pipe was kept in constant motion so as to reach all parts of the bath. This operation resembles the practice of the copper refiners in eliminating base metals from the Doré bullion resulting from the melting of the slime from the electrolytic copper-refining tanks, except that they generally use both sodium nitrate and soda as well as air to eliminate selenium and tellurium.

Slag and bullion samples were taken every half hour, the first being taken at the beginning of the refining period. The fineness of the final bullion was determined by the bullion essays on the bars shipped from each melt.

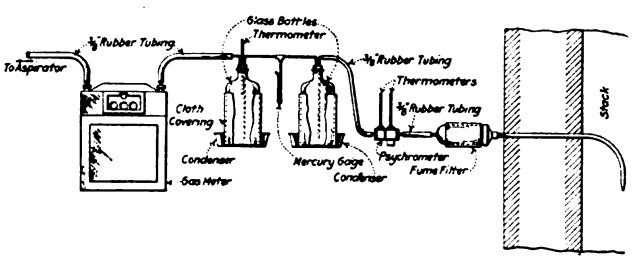

FIG. 1.—GENERAL ARRANGEMENT OF APPARATUS.

The volatilization losses were estimated from the data secured by filtering a measured volume of the flue gases through paper extraction thimbles, and ascertaining the total volume of the flue gases by Pitot tube readings. The general arrangement of the apparatus used is shown in Fig. 1 and details of the fume filter and psychrometer in Figs. 2 and 3.

The fume filter was originally constructed according to the drawings given in an article by Touzalin.[1] In this design the plug 1 is tapered and fits into a similar taper in the shell 2. The filter thimble is slipped over the plug and placed in the shell, the whole being made tight with the nut 3. This form of filter was found unsatisfactory for two reasons. Unless the nut 3 is tightened excessively so that the filter paper is highly compressed, air is drawn into the apparatus through the filter paper between the plug and shell; it is also obvious that a uniform diameter and thickness of thimble is necessary with the Brady type of filter. The dimensions of the thimbles now on the market

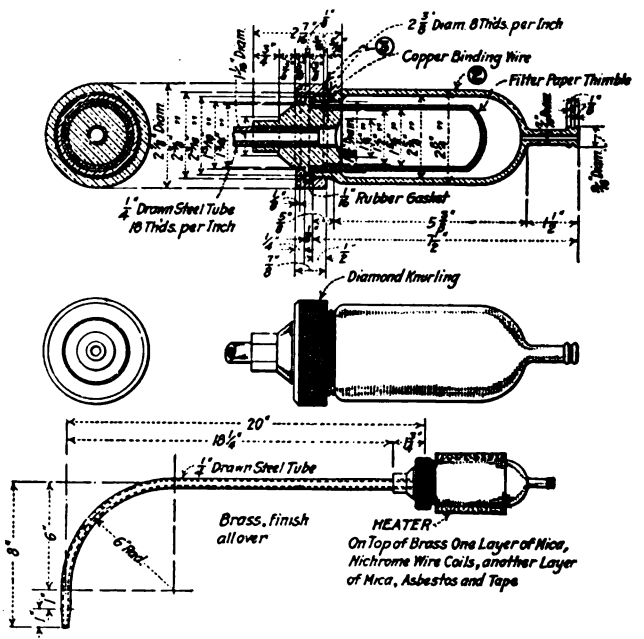

FIG. 2.—DETAIL OF FUME FILTER.

vary considerably. After encountering these difficulties, the form of filter shown in Fig. 2 was adopted. The plug in this has no taper and the thimble is fastened to it by a copper wire. The rubber gasket between the nut and shell gives an airtight joint without the use of wrenches and no difficulty is experienced with the ordinary variations in thimble dimensions.

The glass bottle condensers shown in the general arrangement are necessary because the flue gases carry considerable water vapor. This is especially true immediately after the charging of the wet precipitate. The gas as measured by the meter is saturated at the pressure and temperature obtaining, the excess water collecting in the condensers, where it is measured and its volume at stack conditions calculated. The high water-vapor content of the gas makes it necessary to heat the thimble at times in order to prevent condensation of water upon it.

The volume of the stack gases was calculated from Pitot-tube readings made with a standard Pitot tube manufactured by the American Blower Co. and an Ellison differential draft gage. Exploration tests were made upon the stack to determine the ratio of the average to the maximum Pitot-tube reading, all readings during the actual tests being taken at the point of

[1] L. A. Touzalin: The New Brady Gas Filter. *Jnl. Ind. & Eng. Chem.* (May, 1919) **2**, 312–3.

Digitized by Google

maximum velocity. The precaution was taken in every case to maintain the average velocity in the sampling tube the same as the velocity in the stack at the point of sampling.

The temperature of the flue gases was determined by a base-metal thermocouple used in conjunction with a Leeds & Northrup potentiometer-type indicating pyrometer.

Gas analyses were made from time to time, employing the well-known Orsat apparatus. These data were necessary for the accurate calculation of the total volume of the flue gas.

In the series of tests made from March 3 to 6, each thimble was used until the suction pressure increased to about 5 in. of mercury, when it was replaced by a fresh thimble. In the remainder of the tests, the thimbles were changed and the water in the condensers measured at the beginning of each period of charging the precipitate.

The tests from May 3 to 6 were made while the large furnace was in operation, while all those in which air refining was done were made in the small furnace. The stack capacity was too small for the large furnace, therefore the combustion was imperfect and considerable soot and carbon monoxide were present in the stack gases. This stack, which is a relic of patio-process days, is to be replaced by a new flue system of ample proportions. The small furnace is much nearer to the stack and therefore, because of better draft, combustion is nearly perfect. On account of

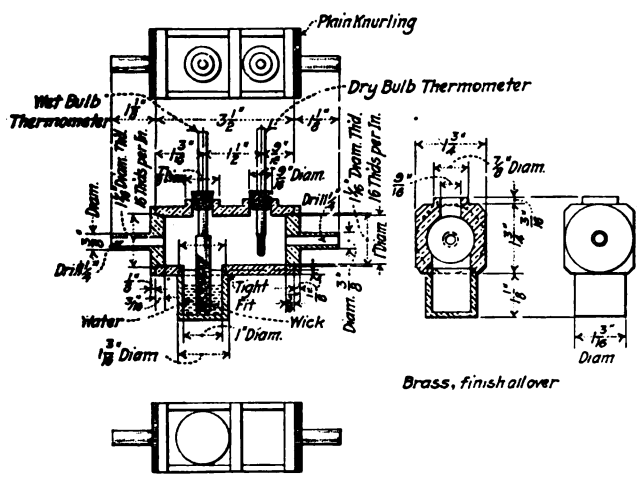

FIG. 3.—DETAIL OF PSYCHROMETER.

less cooling surface, the stack gases from the small furnace are at a much higher temperature than those from the large furnace and at times this temperature was sufficiently high to cause clogging at the tip of the sampling tube, due to a slight sintering of the fume. When this occurred a sharp increase in the suction resulted and the tip was immediately cleaned.

A summary of the volatilization and dust-loss determinations is given in Table 1. It will be observed that there is a considerable variation between the results of the different tests. This is to be expected, as there can be no rigid control of furnace operation and certain factors—for example, dusting—may vary considerably from charge to charge. It is therefore difficult, if not impossible, to deduce definite laws governing these losses; however, certain general conclusions which are of value may be drawn from the results. It should be noted that the melting period in this experimental work was in some cases longer than in the regular practice, and therefore the percentage losses in these cases are correspondingly greater. At times a small amount of fume escaped through the work door on account of poor draft.

The losses are surprisingly small when it is considered that the precipitate is melted in reverberatory furnaces without briquetting. The average loss of silver is 0.1074 per cent., and of gold is 0.02805 per cent., for the Loreto precipitate during melting. The average loss of silver is 0.0625 per cent., and of gold is 0.0150 per cent., for the Guerrero precipitate during melting.

The average loss of silver is 0.0497 per cent., and of gold is 0.0133 per cent., during air refining of Loreto bullion. The average loss of silver is 0.0156 per cent., and of gold is 0.00387 per cent., during air refining of Guerrero bullion. These are average losses for the whole period of air refining which in every case was prolonged more than necessary in order to make sure that the end had been reached. The loss of both silver and gold is considerably greater during the melting of the precipitate and the air refining of the bullion with Loreto precipitate than with Guerrero precipitate. The ratio of silver loss of Loreto to Guerrero for the whole of the precipitate melting period is 1.72 to 1 and the ratio of gold loss is 1.81 to 1. Taking the average hourly losses, the ratio for silver is 1.37 to 1 and for gold is 1.54 to 1.

The ratio of silver loss of Loreto to Guerrero for the whole air-refining period is 3.2 to 1 and the ratio of gold loss is 3.44 to 1. Taking the average hourly losses, the ratio for silver is 4.03 to 1 and for gold is 4.22 to 1.

It will be observed that this difference is sufficiently consistent to preclude its being due to experimental error or variation of conditions in the furnace. We are unable to give a definite reason for this phenomenon but it is of significance that the Guerrero precipitate contains more lead and copper than does the Loreto precipitate. We also have had other evdience which indicates that certain base bullions show less loss by volatilization during melting and holding a charge of molten metal in the furnace than does refined silver. The effect of lead upon the amount of silver carried over in the distillation of the zinc crusts from the Parkes process has been investigated by Dewey,[2] who says that "lead protects the silver from the drag of the volatilizing zinc."

The losses during the melting of the precipitate

[2] F. P. Dewey: Silver Volatilization in Smelting. *Eng. & Min. Jnl.* (July 19, 1919) **103**, 87.

Digitized by Google

appear to be independent of the hearth area of the furnace. This also appears to be the case during air refining of the bullion, but our data are not sufficiently complete to justify more than the statement that the indications are in this direction. It was found that the volatilization losses during remelting of the bullion are relatively high per unit of time as compared to those when melting precipitate, but as the time required is short the total percentage loss is small. None of the bullion is remelted in regular practice.

to 1. The ratio of silver to gold in the fume both during melting of the precipitate and air refining of the bullion shows a very wide variation ranging from 300 to 2400.

These experiments demonstrate that there would be no difficulty in eliminating by simple air refining without the use of fluxes practically all the base metals with the exception of a portion of the copper. This gives a Doré bullion that is well suited to electrolytic refining.

TABLE 1.—*Summary of Volatilization and Dust-loss Determinations*

NOTE: All percentage losses are based upon the metal contents of the shipping bars actually produced.

The two tests upon air refining of Guerrero bullion indicate that the silver losses per unit of time during this period are not greatly influenced by the method of applying the air. The high-pressure air, however, eliminates the bases more rapidly so that maximum refining possible is reached more rapidly than with the low-pressure air, with, therefore, a smaller total loss. The gold losses appear to be distinctly greater with the high-pressure air than with the low-pressure air.

The ratio of silver to gold in both the Loreto and Guerrero precipitate will average approximately 165

The slag and bullion assays and analyses for a typical air-refining test on Guerrero bullion are given in Table 2. It will be noted that there is a rapid elimination of base metals during the first three hours—or up to about 985 fine—after which the elimination is slow. This is typical of the Guerrero bullion when using either low- or high-pressure air, except that, when using high-pressure air, the time required to reach this point is only about one-half that required with low-pressure air. The slag volume, as might be expected, decreases rapidly with the increase of bullion fineness.

Digitized by Google

The composition of the Loreto precipitate is such that the greater part of the base metals combine with the slag during melting and are thereby eliminated, giving a bullion of 970 to 980 total fineness silver and gold before air refining. The total fineness can be increased to over 990 by air refining.

TABLE 2.—*Typical Air-refining Test on Guerrero Bullion*

| Sample | Assays, Kilograms per Metric ton | | Analyses, Per Cent. | | | | |
|---|---|---|---|---|---|---|---|
| | Ag | Au | Cu | Pb | Zn | $Fe_2O_3$ $Al_2O_3$ | Insoluble |
| **Slags** | | | | | | | |
| Slag from melting precipitate | 1.201 | 0.0055 | | | | | |
| Skimmings after: | | | | | | | |
| 1st hour air | | | 2.12 | 57.0 | 12.4 | 17.4 | 5.4 |
| 2nd hour air | | | 3.01 | 55.1 | 7.6 | 17.8 | 13.9 |
| 3rd hour air | | | 6.23 | 52.9 | 5.8 | 19.6 | 15.2 |
| 4th hour air | | | 8.66 | 47.8 | 4.2 | 23.2 | 15.4 |
| 5th hour air | | | 10.50 | 43.1 | 3.8 | 26.0 | 16.2 |
| 6th hour air | | | 12.20 | 37.5 | 2.6 | 25.2 | 17.8 |
| 7th hour air | | | 9.40 | 32.8 | 2.4 | 26.4 | 21.5 |
| 8th hour air | | | 8.90 | 29.0 | 2.0 | 25.8 | 24.6 |
| 9th hour air | | | 9.3 | 26.9 | 2.0 | 25.0 | 26.3 |
| 10th hour air | 125.336 | 0.091 | 9.3 | 22.3 | 2.0 | 20.4 | 27.6 |

**Test Bars**

| Sample | Dore, Parts per 1000 | Ag, Parts per 1000 | Au, Parts Per 1000 |
|---|---|---|---|
| At start of blowing | 935.14 | 929.60 | 5.54 |
| After blowing: | | | |
| 0.5 hr | 951.82 | | |
| 1.0 hr | 963.10 | | |
| 1.5 hr | 970.92 | | |
| 2.0 hr | 979.98 | | |
| 2.5 hr | 984.76 | | |
| 3.0 hr | 986.52 | | |
| 3.5 hr | 985.66 | | |
| 4.0 hr | 986.16 | | |
| 4.5 hr | 986.96 | | |
| 5.0 hr | 989.68 | | |
| 5.5 hr | 987.62 | | |
| 6.0 hr | 987.94 | | |
| 6.5 hr | 988.60 | | |
| 7.0 hr | 988.32 | | |
| 7.5 hr | 988.82 | | |
| 8.0 hr | 990.28 | | |
| 8.5 hr | 987.68 | | |
| 9.0 hr | 989.28 | 983.42 | 5.86 |
| Average of shipping bars | | 980.974 | 5.956 |

The percentage of silver and gold in the Guerrero precipitate is higher than in the Loreto but the proportion of lead and copper is also higher, so that melting of the precipitate produces bullion of a total fineness of but 933 to 938. The total fineness can be increased to 980 to 985 by air refining.

We are indebted to the management of Compania de Real del Monte y Pachuca for permission to publish these results and to George S. Embury, general superintendent of mills, for helpful coöperation in making the tests.

## Eliminating Waste in Estimating

A REPORT on quantity surveying and payment for estimating, with recommendations to owners and investors, architects, engineers and contractors, has been approved and adopted by the American Institute of Architects, American Engineering Council of the Federated American Engineering Societies, and the Associated General Contractors of America.

The purpose of this report is to acquaint prospective owners and others financially interested in building and other construction projects with the wasteful duplication and consequent expense involved in the preparation of estimates of quantities under the systems now generally in vogue. The recommended procedure of quantity surveying is intended to eliminate the present wasteful and uneconomical methods by concentrating the function of determining and compiling the quantities and list of work involved in one agency for each project, this quantity survey to be submitted to all bidders with the plans and specifications. Specific recommendations are:

1. *Quantity Surveying.*—Architects, engineers and contractors should jointly use their efforts to have established facilities for making quantity surveys.

2. *Payment for Quantity Surveying.*—The owner should pay for the quantity survey from ¼ per cent. to 1 per cent. of the cost of the project for commercial and public work and not more than twice as much for residence work, whether the project is constructed or not.

3. *Cost of the Project.*—The cost of the project may be defined as the accepted bid, or in cases where no bid is accepted, the bid of the lowest responsible bidder as determined by the architect or engineer. However, in cases where alternate bids are required, the additional payments for the quantity survey shall be based upon the additional quantities surveyed, as approved by the architect or engineer.

4. *Altered Plans.*—Altered plans which involve a change in quantities after the quantity survey has been made justify an addition to the original fee for quantity surveying.

5. *Basis of Contract.*—Owners should have the option of: (*a*) Making the quantity survey a part of the contract; (*b*) permitting the successful bidder, at his own expense, an opportunity to verify the accuracy and completeness of the quantity survey before the contract is signed. If he proves errors to exist in the quantity survey, the bidder shall be permitted to adjust his bid accordingly.

6. *Unit Quantities and Standards.*—The schedule of unit quantities should conform to local customs or methods of measurement and should be so stated on the quantity survey. The eventual adoption of national standards is recommended.

7. *Guarantee.*—The guaranteeing of quantities by a quantity surveyor is not recommended, for it might

Digitized by Google

influence the surveyor to protect himself by increasing the quantities. The extra cost of a guarantee would not be warranted.

8. *Existing Methods.*—The cost to owners of preparing bids by existing methods, which make necessary wasteful duplication in estimating quantities by several bidders, is known to be much greater than the cost of preparing bids based on a quantity survey furnished by the owner, and therefore such existing methods are condemned and should be discontinued.

## Steel Ingot Capacity of United States

THE *Iron Age* on Dec. 8, 1921 gives the following figures on the ingot capacities of the various steel companies in the United States:

| | Ingot Capacity, Gross Tons | Per Cent. of Country's Total |
|---|---|---|
| Midvale Steel & Ordnance Co | 2,894,000 | 5.74 |
| Lackawanna Steel Co | 1,840,000 | 3.65 |
| Youngstown Sheet & Tube Co | 1,500,000 | 2.98 |
| Republic Iron & Steel Co | 1,395,000 | 2.77 |
| Inland Steel Co | 1,000,000 | 1.98 |
| Steel & Tube Co. of America | 900,000 | 1.79 |
| Brier Hill Steel Co | 600,000 | 1.19 |
| United States Steel Corporation | 22,700,000 | 45.00 |
| Bethlehem Steel Corporation | 3,217,000 | 6.38 |
| Jones & Laughlin Steel Co | 2,640,000 | 5.24 |
| Colorado Fuel & Iron Co | 1,138,000 | 2.26 |
| Other steel companies | 10,620,000 | 21.02 |
| Total for the country | 50,444,000 | 100.00 |

The Steel Corporation's ingot capacity of 22,700,000 tons is considered to represent roundly 45 per cent. of the country's total ingot capacity. Some estimates would give a somewhat higher figure, but 45 and 55 may fairly be taken to represent the Steel Corporation and the independent percentages, the 50,444,000 tons standing for a practically attainable capacity, as distinguished from a theoretical capacity.

## Preparation and Storage of Mine Timbers

BETTER preparation and storage of mine timbers are advocated by the Bureau of Mines. The durability and strength may be considerably increased and the consumption decreased, and thus mining costs may be reduced.

Preparation may be considered under two heads—peeling and seasoning. Peeled timber weighs 6 to 10 per cent. less than unpeeled green timber. Therefore, peeling at point of shipment effects a considerable saving in cost of freight. In comparatively dry workings, peeling will increase the life of timber appreciably; in wet places, this is not so apparent. In dead timber, the space beneath the bark is an ideal breeding place for wood-destroying insects. Bark also retains moisture and thus promotes fungus growth.

Records of actual tests show that thoroughly seasoned timber may be from 25 to 50 per cent. stronger than green timber of similar varieties. Under some conditions, seasoning increases the durability, but in general seasoning without preservative treatment does not add greatly to the life. Like peeling, seasoning decreases the weight. Experiments by the Forest Products Laboratory, Madison, Wis., have shown that round mine timbers up to 11 in. in diameter air-seasoned 3 mo. lost 15 to 25 per cent. of their original green weight, depending upon the size and variety of the timber. In general, mine timbers may be sufficiently air seasoned for most purposes in 3 to 6 mo., depending upon the weather, locality, and variety of timber. Timber that is to be treated must be seasoned, as the preservative fluid cannot be injected until at least a part of the water which green timber contains is expelled.

Proper storage is essential for proper seasoning, also for preventing checking and initial decay before placing the timbers in service. Timber yards should be well drained and free from vegetation and decaying wood. Timber should be placed on supports at least 12 in. from the ground, and should be so piled that air can circulate freely.

## Associated Scientific and Technical Societies of South Africa

"DURING the year, great strides have been made toward the realization of the scheme for a joint home of the scientific and technical societies" in South Africa, says the *Journal* of the Chemical, Metallurgical & Mining Society of South Africa. "The premises which had recently been acquired at the date of the last Annual Meeting are now known as the Scientific and Technical Club. They have been put into thorough repair and well fitted and furnished throughout, while a restaurant and tea room have been opened for the convenience of members, and it is expected that the club bar will be opened in the beginning of next month. Generous donations to the funds of the associated societies have been received from members of this Society and their friends, and it is hoped that they will also patronize the club on every possible occasion. Now that the ideal of "closer working and joint housing" has so nearly approached achievement, it is incumbent upon every member of each society concerned to do his utmost to make certain of the ultimate success of the scheme. In February last, this Society transferred its offices from the University College Buildings to the club premises."

# Bituminous Industry Drifting Toward Further Trouble

By EUGENE McAULIFFE
President, Union Colliery Co., St. Louis, Mo.

SINCE 1917, the bituminous coal industry has surged, violently at times, across the nation's social, industrial and economic foreground. Today a silent, yet more active, force is working within the industry, and the movement now taking place, if allowed to continue, will cause serious consequences when coal is again wanted at the rate of 550,000,000 tons annually instead of at the rate of 400,000,000 tons, the apparent requirement for 1921. I refer to the shift of tonnage from the highly unionized fields of Pennsylvania, Ohio, Indiana and Illinois to the non-union fields of Pennsylvania, West Virginia, Alabama and certain western states, and to the so-called union fields in Kentucky and Colorado, on which the union saddle rests lightly. This movement, in the absence of the usual winter transportation shortage, is taking place rapidly and will be accentuated if, as is probable, work is suspended in the union mines on March 31 next. This drift of tonnage has been made possible by the unit wage reductions in the non-union fields and by the modification of the so-called conditions that have been saddled on all mines wherever the United Mine Workers have gained a foothold; these changes permitted the first reduction in mine cost, which made possible the securance of contracts; better running time assisted in making further reductions, and the transfer of tonnage served to increase the unit cost in the field from which it was transferred. This situation not only opposes the highly unionized operation but brings about a transfer of traffic from the roads serving such mines to those that serve in a primary or secondary manner the more favored localities.

The net result is evidenced in (*a*) the migration of union labor to the non-union mines; (*b*) the deterioration and decadence of union properties; (*c*) the necessary curtailment in the purchase of new equipment and in the maintenance of existing equipment and track facilities on the part of the carriers serving the union fields. This, in turn, when business is restored to normal or to the point above normal that invariably follows an adverse swing of the business pendulum, will cause (*d*) a shortage of coal and coal transportation facilities; (*e*) an era of coal speculative debauchery with exorbitant prices and serious deflection in the matter of quality; (*f*) a period of labor unrest followed by demands for increased wage rates supplemented by a marked loss in individual efficiency, with resultant strikes, business unrest, and the pressure of new economic theories.

In 1918, the labor status with respect to relative tonnage produced was approximately as follows: produced in highly organized fields, 62 per cent.; produced in partly organized fields, 21 per cent.; produced in unorganized fields, 17 per cent.

During the strike of November and December, 1919,. the mines that remained at work attained 35 per cento of the nominal production of soft coal, a situation made possible by the migration of union labor to non-union mines and the concentration of the nation's coal transportation facilities on the rails of the carriers serving the non-union fields. The history of the efforts made by the carriers to untangle the car scrambling which took place during this period and which sent the self-clearing battleship type of car into western territory where it could not be readily unloaded, and the western gondola type of car to New England and the seaboard, is yet painfully recalled. This confusion proved a serious factor in the coal car shortage that continued throughout the following year. We are drifting toward a similar situation now, propelled by economic forces rather than by a sudden strike.

## Public and Carriers, Workmen and Operators, Must all be Considered

Any survey that includes merely the men who work in the mines and the operators who employ them, and that ignores the requirements of the public and the ability of the carriers to furnish the required transportation, can not be considered more than a casual one, and cannot be depended upon as a foundation for betterment. Several months ago the imperative necessity for the liquidation of the high wage scales paid in the union fields was suggested, and although it was urged by our national administration the United Mine Workers, through their leaders, replied with a curt refusal. As a result, the whole organization now stands in a fair way to suffer dissolution—a consummation that, however devoutly it may be wished for by many, is of doubtful value to the producer who seeks stability of investment and a fair return.

Many who have had extended experience in the coal industry view with concern the possibility of absolute non-unionism. No doubt such a state would prove a paradise temporarily to many who have suffered the

Digitized by Google

ruthless domination of the unions, but the feeling is well established that any such apparent paradisiacal residence would be short lived, and that it would be only a few months until the temptation of temporary heavy market demand and high prices would shift many producers to the purgatorial zone of labor buying on the part of the predatory producer, from the operation of his more conservative neighbor, which would create as many wage scales as there were mines, and from which the descent into the hades of a new, revivified, and perhaps even more radical organization would prove but a short step.

Speaking broadly, the coal industry, however depressed the position it may occupy temporarily, must be kept in a healthful condition, and serious and far-reaching distortions in the scheme of distribution should not be allowed to enter it. No doubt many changes of value could be made in the present market zones, but they should be made with a view to securing the maximum economy in ultimate fuel costs, one of the major items of which is transportation. The conservation of the gross ton miles expended in the transportation of the nation's fuel represents a task as important as that of securing the maximum possible thermal return from the coal consumed, for gross ton miles mean the absorption of fuel as well as human effort.

The temporary shifting of business from nearby fields of production to those more remote, forced by an artificial economic pressure, does not represent a sound foundation on which to build a returning prosperity and there is crying need today for the collection and compilation of accurate and dependable information concerning the coal industry, which will, when made public, point the way toward a cure for some of the ills from which coal habitually suffers, and assist it toward the position that its magnitude and importance should permit it to occupy.

## Cost of Producing Pig Iron

IN AN article on The Manufacture of Pig Iron in the *Griffin Bulletin* of November, published by the Griffin Wheel Co., Chicago, G. S. Evans, superintendent of the cupola division, presents estimates of the cost of making pig iron in the three principal producing centers, based upon materials acquired at current market quotations:

| | Pittsburgh | | Chicago | | Birmingham | |
|---|---|---|---|---|---|---|
| | Tons | Value | Tons | Value | Tons | Value |
| Ore | 1.8 | $12.42 | 1.8 | $10.17 | 2.7 | $4.89 |
| Limestone | 0.4 | 0.48 | 0.4 | 0.48 | 0.4 | 0.40 |
| Coke | 1.0 | 4.50 | 1.0 | 7.00 | 1.6 | 8.00 |
| Mis. supplies and relining | | 0.81 | | 0.81 | | 0.94 |
| Labor | | 1.08 | | 1.08 | | 1.35 |
| Cost per gross ton | | $19.29 | | $19.54 | | $15.58 |

## Specifications for Steel Forgings

AMONG the eleven standards of the American Society for Testing Materials now before the American Engineering Standards Committee for consideration and approval are:

Specifications for Carbon-steel and Alloy-steel Forgings (A18-21).

Specifications for Quenched and Tempered Carbon-steel Axles, Shafts and other Forgings for Locomotives and Cars (A19-21).

Specifications for Carbon-steel Forgings for Locomotives (A20-21).

Specifications for Quenched and Tempered Alloy-steel Axles, Shafts and other Forgings for Locomotives and Cars (A63-21).

Specifications for Carbon-steel Car and Tender Axles (A21-18).

Specifications A18-21 for carbon-steel and alloy-steel forgings are general specifications covering the various classes of carbon-steel and alloy-steel forgings, on which the other specifications have been based with the addition of special requirements to suit the conditions of use. The preparation of these four specifications for forgings dates back to the earliest history of the American Society for Testing Materials. The predecessor of these specifications was the "Standard Specifications for Steel Forgings," which were first proposed in 1900 and adopted in 1901, previous to the organization of the present A. S. T. M., by what was then the American Section of the International Association for Testing Materials. Since 1901, there have been several revisions of the work, notably in 1914 with the coöperation of other technical societies and associations, including the former Master Mechanics Association and the Master Car Builders Association, now the Mechanical Section of the American Railway Association. The work on alloy-steel forgings other than nickel steel was developed, in 1915, as an extension of the previous work.

The specifications for carbon-steel car and tender axles, while not included in the forgings series, were developed in connection with this work. In 1914, the Committee of the American Society for Testing Materials in charge of these specifications entered into a coöperative investigation with the Master Car Builders Assn., which led to a revision of the specifications, in 1917, that harmonized the requirements in the two organizations. The revised specifications, adopted in 1918, have stood without revision since that date.

In submitting these specifications for approval by the American Engineering Standards Committee, the American Society for Testing Materials has presented data listing the companies, etc. that use them in their entirety or as general specifications on which have been based other specifications suited to particular needs. These specifications have been translated by the Department of Commerce into French and Spanish in connection with the development of foreign trade.

# Revision of the Mining Law

By F. F. SHARPLESS

Secretary of the American Institute of Mining and Metallurgical Engineers

IT IS to be read in Western newspapers that Hon. S. S. Arentz, who introduced H. R. 7736, has repudiated it, that certain mining men in Utah and Nevada say that they will fight it "until hell freezes over." It is to be read in more temperate expressions that "the eminent engineers who drafted the bill exhibited a woeful misunderstanding of Western sentiment and opinion." Furthermore, it is averred that there is no need for revising the mining laws, that we have got along pretty well under the existing laws, etc. Such statements are so surprising in view of the facts of record that it is hard to believe that the opponents of the bill, who make them, are well informed, or that they represent general opinion. It will be useful therefore to review the record of the case.

## Our Good Old Mining Laws

We have indeed got on well in our mining industry, but that has not been by virtue of our good old mining laws. Rather has it been in spite of them. Ever since the Richmond-Eureka case in the '70s there has been litigation arising from them. Early in the '80s the apex law was discarded by common consent in Leadville, and it has been ignored in every district of flat-lying ore deposits ever since. The great mines of the present time are the porphyry copper deposits. At Bingham, Ely, Ray, Chino, Miami, Clifton and Ajo the apex law is simply inapplicable. A law that is inapplicable to the modern conditions of mining may be an old law, but it can not properly be characterized as a "good" law.

For such reasons, and many others of weight, there has been a demand for revision of the mining laws dating back at least three decades. President Roosevelt appointed a commission to advise respecting the question, said commission comprising Dr. James Douglas (chairman), John Hays Hammond, D. M. Barringer, Walter B. Devereux, and William B. Mather. This committee was unanimous on the following points:

(1) That the provisions of the existing law of the apex should be replaced by a law limiting the possession of minerals in depth by both the end and the side lines carried down vertically. (2) That all mineral and coal lands be laid out and located on the present legal subdivisions applied to agricultural lands wherever possible, and where not possible on lines conforming therewith as nearly as may be, and therefore with lines running always true north and south, east and west. (3) That an official Government map of every mining district be preserved in the nearest county recorder's office, and that within six months of the location of the claim it should be surveyed by a Government surveyor and plotted on said map. (4) That the unit of a mining claim be $\frac{1}{16}$ of the agricultural quarter section, which would be about 660 ft. square (*i.e.*, 10 acres).

In 1911, the Mining and Metallurgical Society of America took up the agitation and appointed a committee under the chairmanship of H. V. Winchell to study the subject of revision of the mining laws, and report.

In 1914, Senator Smoot introduced in the Senate a bill providing "for a commission to codify and suggest amendments to the general mining laws," which was reported out of the Committee on Mines and Mining by Senator Walsh, on March 16, 1914.

In 1915, on Dec. 16, following prolonged discussion of the subject within the Mining and Metallurgical Society, a convention of mining men, largely attended, was held in the Auditorium of the Smithsonian Institution in Washington under the auspices of the Mining and Metallurgical Society of America, the American Institute of Mining Engineers and the American Mining Congress, in collaboration with the Idaho State Mining Association, the Montana Society of Engineers, the California Metal Producers' Association, the Spokane Mining Men's Club, the Nevada Mine Operators' Association and the Colorado Scientific Society, with representatives from several Chambers of Commerce and many operating mines.

## The Interest of the Prospector

In the report of this meeting it was stated "there is a class of men as deeply interested as the engineers, if not more so, in securing these changes, *viz.*, the prospectors and small operators, the men who work, but have little time or means for attending such a convention regardless of their interest. These were conspicuous by their absence, but several hundred letters have been received by the secretary from such men, giving their earnest support to the movement and regretting their inability to attend."

The President of the United States showed his interest. The Department of the Interior not only showed interest but arranged in every way possible to facilitate the objects of the meeting. Practically

Digitized by Google

all the senators from the public land states and nearly all the representatives from those states were present at one or more sessions of the convention or indicated by letter their desire to further the objects of the meeting.

The Mining and Metallurgical Society of America presented a set of resolutions, based upon the report of its committee appointed in 1911, the recommendations of which had been put before the members of the society by letter ballot and had been adopted, as to the fundamentals, by practically unanimous vote. The resolutions that had been adopted by the society were as follows:

(1) The mining law should be revised not piecemeal, but thoroughly, so as to coördinate and harmonize its various provisions.

(2) A statute of limitations should establish a reasonable term of years beyond which placer patents shall be immune from attack on the ground of fraud.

(3) Full privilege of appeal to some competent court of law should be provided for in all cases of contests between rival claimants, or between a locator and the Government.

(4) Notice of mining locations should be so recorded as to give the fullest possible public notice.

(5) The apex law should be abolished.

(6) Existing titles should be reaffirmed and fully recognized and no effort should be made to create retroactive legislation.

(7) For the purpose of giving the fullest consideration to the needs of every branch of the mining industry and every section of the country, it is desirable that a Government commission be created by act of Congress, whose duty it shall be to investigate by every proper means the questions and interests here referred to, and to make recommendations as a basis for the proposed mining law revision.

Similar resolutions, of the same general thought and purport, were presented by the American Institute of Mining Engineers, the American Mining Congress, the Montana Society of Mining Engineers, the Utah Chapter of the American Mining Congress, the Pioche Commercial Club and the Spokane Mining Men's Club. The secretary of the Mining and Metallurgical Society reported that ten Chambers of Commerce had written letters approving the plans of the convention and had appointed delegates to attend. About 300 letters had been received by him, and more by the chairman of the committee on revision of the mining laws, from prospectors, operators and mining companies, approving the plan of instituting a revision of the mining laws. Fifteen letters had been received favoring the apex law, but objecting to other features in the existing statutes. Only three letters had been received advising that no alterations of the existing laws be made.

### Convention Advices against Piecemeal Revision

The convention ended its work by adopting the resolutions offered by the committee on resolutions, the essence of which was that "the mining law of the United States should be revised, not piecemeal, but thoroughly, so as to coördinate and harmonize its various provisions; and that a Government commission be created by act of Congress for this purpose."

Up to this time the aspirations and efforts had been directed toward the creation of a Government commission by act of Congress. This had unfortunately introduced the questions of expense and objectionable features that are so often associated with Congressional commissions, and Congress evinced an unwillingness to take such a step. The Mining and Metallurgical Society of America, however, retaining the leadership that it had taken, was unwilling to let the matter drop, and throughout 1916 continued its discussion of the subject, at the same time inspiring the Western state and local societies to continue their discussions. The record of these practically fills the volume of proceedings of the Mining and Metallurgical Society of America for 1916. The discussions crystallized in the submission to the members of the society of a list of 33 specific questions as to how the mining law should be revised. The same list was submitted to all of the organizations that participated in the Washington convention. Upon the fundamental principles that the law of the apex should be abolished, that discovery should no longer be requisite as a preliminary to location and that the phraseology and principles of administration of the present laws should otherwise be preserved to the maximum possible, there was practically a unanimous vote in the Mining and Metallurgical Society of America, the Northwest Mining Association, the Nevada Mine Operators' Association, and the California Metal Producers' Association to which the same questions had been submitted in substantially the same way as in the M. M. S. A.

### Appointment of Bureau of Mines Committee

During all these years and in the foregoing ways the subject had been pretty thoroughly thrashed over. It remained for somebody to embody ideas in a specific bill for the purpose desired which would enable discussion to be focused upon provisions in detail. It had been asked that a Congressional commission be created with that object in view, but hope of obtaining such a commission having been abandoned, it was arranged in conference between Van H. Manning, then director of the United States Bureau of Mines, and Doctor Foster, then chairman of the House Committee on Mines and Mining, to create a committee within the Bureau of Mines. Thus, the mining industry got substantially what it had asked. It had applied for a Congressional commission and it obtained a Governmental committee, which amounted to about the same thing. Director Manning invited the coöperation of the council of the Mining and Metallurgical Society of America with respect to the constitution of the committee, and upon its advice he appointed W. R. Ingalls (chairman), Walter Douglas (vice chairman), Hennen Jennings, John Hays Hammond, James R. Finlay, J. Parke Channing, and L. D. Ricketts. H. V. Winchell took

Digitized by Google

the place of Mr. Jennings after the death of the latter. The committee served without remuneration and in the capacity of consulting engineers for the United States Bureau of Mines. The Bureau furnished the committee with a secretary.

The committee thus organized owed responsibility to nobody but the Federal Government. It was not bound by any expressions of opinion that had been made, or resolutions that had been passed previously by societies. Its sole duty was to draft a bill providing for revision of the mining laws that would in its judgment provide best for the mining industry and the national welfare. The prolonged discussions that had preceded the entry by the committee upon its work may be considered as corresponding with the hearings that would have been given by a traveling commission, but probably they were far more comprehensive and representative than would have been heard by any traveling commission.

In considering the work of the committee, it is desirable that the history of the movement toward revision of the mining laws be kept in mind. Some of the critics of the bill drafted by the committee appear to have lost sight of this and also of their own previous actions. Thus the Northwest Mining Association recently passed a resolution which is quoted below. Attention is drawn particularly to the action of this association because it has expressed itself in a concise well ordered resolution which contains about all the objections that have been offered; because on almost every point it reverses its action of a few years since; because a large number of its members are members of the Institute, men whose opinions are worthy of serious consideration; and because these members, having expressed themselves strongly for the revision of the mining law, the Institute supported them, only now to find that it supported something that is apparently offensive to them.

### Reversal of Northwest Position

The resolution passed by the association reads as follows:

Whereas a bill to revise, amend and codify the laws of the United States, relating to the location of mining claims on the public domain, is now before the Sixty-seventh Congress and known as H. R. 7736; and

Whereas, the purposes and probable effects of this bill, if enacted, have been carefully studied by competent committees of this Association and have been adversely reported upon; and

Whereas, the existing Federal mining laws are now well and generally under tood, as interpreted by the courts in the last forty-nine years, and have not proved to be sufficiently defective to require drastic revision, now therefore

Be It Resolved: That the Northwest Mining Association, representing mining interests in the states of Montana, Idaho, Washington and Oregon, at a regular meeting in Spokane, Washington, Nov. 19, 1921, does hereby respectfully protest the passage of this bill on the ground that it is not competent to improve present mining conditions but that, on the other hand, it would doubtless prove burdensome and intolerable in several respects and make confusion worse confounded, as shown by the attached analysis which is hereby made a part hereof.

In the attached analysis by Frank A. Ross, chairman of the committee upon whose report the above resolutions were based, objection is made to the requirement in the committee's bill that locations must conform to the public land surveys; that it compels the filing of location notices, proofs of assessment work, etc. in the United States Land Office only; that it provides for the acceptance of cash payment in lieu of assessment work on a claim; and that it permits location without discovery. Furthermore, objection is raised to change from the present method of obtaining mill sites and finally opposition is expressed "to any tampering with the well established extralateral right."

### Committee on Revision an Advisor not an Advocate

It is to be presumed that the committee of the U. S. Bureau of Mines, functioning as a governmental agent, will not enter into any discussions. Its position is, probably, that it has made its report, and given its advice as to what in its judgment is best. If the mining industry does not want to conform to the committee's judgment, Congress will surely not pass any bill in opposition to the popular wish. Nor will the committee press for any such action. The committee is not an advocate, but rather is an advisor. If Congress after hearing objections that have been raised should request the advice of the committee, the latter would no doubt say with respect to some objections that they are of trifling nature and they might cheerfully be allowed to prevail if the people want to have things in a different way. This would be analogous to the position of a physician who has advised a patient to give up smoking, but yielding to the pleading of the patient allows him to continue the habit, telling him that he would be better without it but will not come to any great harm by continuance.

Probably the committee would so view the matter of cardinal locations, or the optional payment of assessments by the alternatives of cash or work. But the Northwest Mining Association challenged the committee in fundamentals, *viz.*, on the subjects of extralateral rights and abolition of discovery as a prerequisite to location. In fact, the Northwest Mining Association deprecates any revision of the mining laws at all. Yet the Northwest Mining Convention held in Spokane, March 20–25, 1916, passed resolutions declaring the existing mining laws to be unsuited to present needs and to have developed various evil and radical defects that sorely retard or wholly impair the development of our mineral resources; and asking that Congress enter upon the subject of revision; which report was signed by Frank A. Ross as chairman. And at a meeting held Oct. 12, 1916, the Northwest Mining Association, with Frank A. Ross as chairman, declared in resolutions that were then adopted that revision of the mining laws should be undertaken; that the new laws should

Digitized by Google

authorize mineral locations *without* discovery in any part of the public lands officially classed as mineral; that the abolition of extralateral rights be strongly urged; and that in lieu of the performance of actual assessment work the owner (of a claim) should be permitted to make a cash payment.

In fact, careful reading of the whole set of resolutions adopted by the Northwest Mining Association, Oct. 12, 1916, discloses that the committee of the United States Bureau of Mines incorporated most of its thoughts, and when departures therefrom were made they were undoubtedly to accomplish reconciliation with the thoughts of other bodies of mining men. For in our republican form of government it is obvious that everybody can not have everything in his own way and maintain that he alone is right. The Northwest Mining Association offers no explanation with respect to the discrepancy between its actions on Oct. 12, 1916 and Nov. 19, 1921. Such diametrically opposite views having been expressed, it would appear that the only possible explanations are a complete change of mind, a misunderstanding o the committee's bill, or a captiousness with respect to it. The Northwest Mining Association characterizes the committee's formula for the location of mineral claims without discovery (which five years previously it had approved in principle) as "one of the most vicious pieces of legislation ever proposed for the regulation of land holdings." But it concedes that some *well guarded* provision should be made by which territory lacking visible signs of valuable minerals may be honorably prospected for suspected deposits. Why not, then, instead of merely condemning the committee's formula, suggest something that would be well guarded. Surely, the committee and everybody else would welcome constructive suggestions.

### Present Laws Pitifully Inadequate

Anybody who has read intelligently the committee's report,* which accompanied its bill, can see that the committee in its deliberations thought of a good many things needful in providing for the mining industry of the future that nobody had suggested in the preceding discussions, prolonged and extensive as they were. On this subject, the Northwest Mining Association objects to any change in the present method of obtaining mill sites. The present method which was drafted in the days of the little quartz mill of 50 years ago, permits the acquisition of a pitiful five-acre mill site. There is no provision in the existing mining laws for acquiring the ground necessary for the big plants of the present day, or for the storage of overburden, tailings, etc. Considering such conditions, as the committee has, it seems rather ridiculous merely to say "leave things as they are."

There is another remark that is constantly cropping up to the effect that the existing mining laws are now well and generally understood, as interpreted by the courts, that even if the extralateral features be bad they have done all their harm. This implies that litigation of that kind is ended. If anybody entertains that opinion, let him consult Mr. Winchell, who is an expert in such cases, and ascertain whether in truth litigation has ended, or whether even the end thereof be in sight. To those who think that all difficult cases have been solved, that the complexities of the existing laws have been interpreted by the courts so that everything is now clear, let them also confer with Mr. Winchell, who would welcome advice as to many difficult cases upon which he is engaged.

### Amendments to Present Law Repeatedly Offered

We may well stand aghast if we find it really to be true that the mining industry of the United States after having expressed itself as desiring a revision of the mining laws, and having urged it to the extent of holding meetings and even a general convention to accomplish the purpose, and having had bills leading to that end introduced in Congress by eminent senators and representatives, should now within the space of five years, during which the committee was diligently and patriotically working for the purpose, declare that no revision at all is wanted; that the existing laws are good enough. It would be incomprehensible that the mining industry, speaking truly, should say such a thing as that. Instead of being a case of preserving the old statutes, the fact is that bills amending the existing mining law piecemeal are being introduced all the time. Several bills of that nature have been introduced at the existing session of Congress and have been held back by the committee on mines and mining of the House of Representatives pending the receipt of the committee's bill respecting which the chairman of the committee on mines and mining of the House of Representatives had been kept informed from the beginning. In compliance with pressure from that quarter the committee's bill was given to the congressional committee even before it had been reviewed by the Secretary of the Interior.

Whether the committee has done a good job, or not, is a totally different matter. As to that, opinions may reasonably differ. It is reasonable to ask, however, that before anybody commits himself to an opinion he should give some study to the subject, and not be carried away by some whim, or merely in following some thoughtless or disingenuous leader.

It must be clear to anybody who gives careful study to the committee's work that it has not advanced any whimsical thoughts. Its recommendations are very much in line with those of the commission under the chairmanship of Doctor Douglas, which reported during the Roosevelt administration. It is even more closely in line with the expressions of opinion among the mining

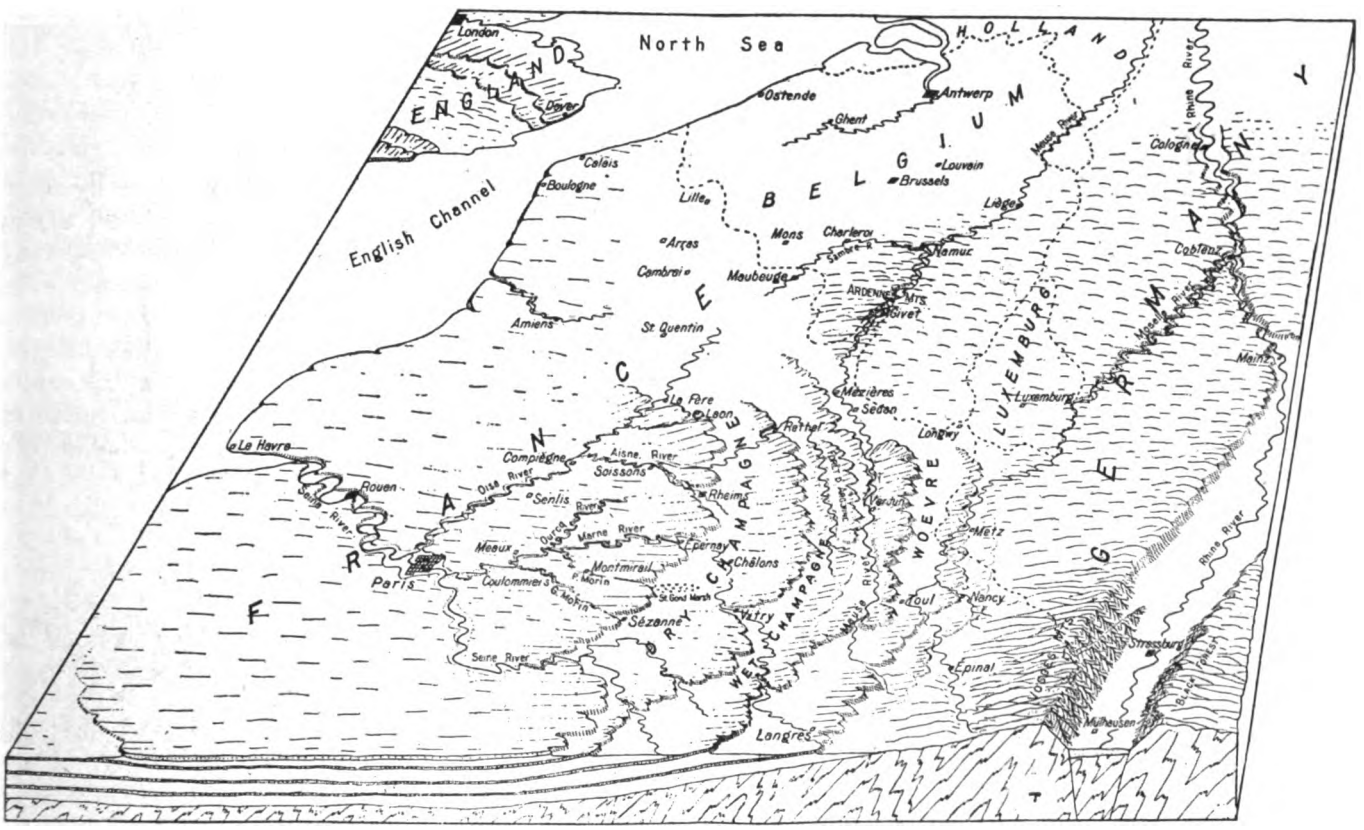
* Printed in full in *Mining and Metallurgy*, October, 1921.

Digitized by Google

societies, national, state and local, developed through the discussions of 1916. The committee does indeed contemplate making the location of mineral lands more orderly than it is at present, but even in that it does not go very far. As a writer in a recent number of MINING AND METALLURGY remarked, the committee's bill will not make people honest, but it will give them a chance to be honest if they want to be. Could anything more severe be said about the existing laws than that they are so framed that people can not be honest even when they want to be?

Douglas W. Johnson, associate professor of physiography in Columbia University, discussed the effect of geology and topography on the influence of strategy of the world war.

"What is now the country of northern France was in time long past a part of the sea," said Professor Johnson. "When the sea-bottom deposits were upraised to form land, the horizontal layers were unequally elevated. Around the margins the uplift was greatest, thus giving to the region the form of a gigantic saucer or basin. Because Paris today occupies the center of this basin-



DIAGRAMMATIC VIEW OF WESTERN THEATER OF WAR, SHOWING PRINCIPAL PLATEAUS AND PLAINS, MOUNTAINS AND LOWLANDS, CLIFF SCARPS AND RIVER TRENCHES THAT INFLUENCED MILITARY OPERATIONS. UNDERGROUND ROCK STRUCTURE IN FRONT.

Instead of condemning the committee's bill, let those who can, set about improving it. Let them be careful about throwing away the opportunity. There is a general codification of the statutes of the United States in progress. Some day the mining laws, which are scattered through the books and are sadly in need of codification, will be reached. The revision then may be done by hands less friendly to the mining industry than those of the present committee of the Bureau of Mines, which is a part of the industry, and as such both knows the business and is sympathetic.

## Influence of Geology and Topography on Strategy of the World War

AT A MEETING of the New York Post of the Society of American Military Engineers held in Engineering Societies Building on Nov. 1, Major

like structure, it is known to geologists and geographers as 'the Paris Basin.'

"Imagine yourself at Paris, and start on a tour of inspection eastward to the German border. First you traverse the central plateau of the Paris Basin. Here and there, you come suddenly upon the edge of a river valley. Descending the steep slopes of the valley wall, which are often clothed in forests, you reach the flat valley floor several hundred feet below, and make your way over the winding stream. Toiling painfully up the slope you at length come out again upon the flat upland of the plateau surface. Pausing to rest, you look back at the obstacle you have just traversed, and reflect that a number of such obstacles cross the plateau in parallel courses from east to west. You realize that they must prove serious barriers to the advance of armies moving southward or northward; and as you remember that

Digitized by Google

two of these obstacles bear the names of the Marne and the Aisne, you have a fuller understanding of two notable chapters in recent military history.

"In surveying the surface features of the western theater of war, we find that the Vosges Mountains, the mountains of western Germany and the Ardennes in Belgium constitute a broad outer zone of comparatively difficult country, within which concentric belts of plateaus with eastfacing scarps defend the most direct approaches to Paris. Only through Belgium into northern France is there a level pathway, free from obstacles, of great breadth most of the way, and provided with every facility for the rapid movement and prolonged sustenance of large armies."

After an illustrated description of the geologic and topographical features of the French theater of war, the specific campaigns were described with especial reference to the topographic features. Professor Johnson is the author of two interesting books, "Topography and Strategy in the War," and "The Battle Fields of France," which take up similarly from a topographical and geological standpoint all campaigns in all of the different strategic operations in the west and in the east.

## Mine-rescue Standardization

ANNOUNCEMENT of the tentative personnel of the various sub-committees of the Mine-rescue Standardization Committee, by George S. Rice, chief mining engineer of the United States Bureau of Mines, and chairman ex-officio of the committee, marks the beginning of the program for definite, practical work toward obtaining international standards in the use of mine-rescue apparatus.

Sub-committee No. 1, on international mine-rescue standards, will act as a liaison committee. Lieut.-Col. J. A. S. Ritson, inspector of mines of Great Britain, has been appointed chairman of this committee. Robert Strachan, senior inspector of mines of British Columbia, is the Canadian representative. J. W. Paul, chief of coal-mine investigations of the United States Bureau of Mines, Pittsburgh, Pa., is secretary. Representatives from Belgium and France will be named later.

Sub-committee No. 2 will deal with rescue-apparatus requirements and tests for permissibility. D. J. Parker, chief of the division of mine-rescue cars and stations of the Bureau of Mines, has been named chairman.

Sub-committee No. 3 will take up the subject of physiological effects in use of mine-rescue apparatus and methods for detection of dangerous gases. Dr. R. R. Sayers, chief surgeon of the Bureau of Mines, is named as chairman. Other members of this committee are Dr. A. F. Knoefel, Terre Haute, Ind., Dr. Yandell Henderson, Yale University, and A. C. Fieldner, superintendent of Pittsburgh Experiment Station, Bureau of Mines.

Sub-committee No. 4 will consider regulations for use of mine-rescue apparatus in coal mines. Robert M. Medill, director of the Department of Mines and Minerals of the State of Illinois, is chairman, and C. A. Herbert, district mining engineer of the Bureau of Mines at Vincennes, Ind., is secretary. E. H. Denny, mine safety engineer of the Bureau of Mines, and Robert Lilly of West Virginia will study regulations for use of apparatus in mines having flat coal beds. Regulations for use of apparatus in pitching coal beds will be taken up by J. J. Forbes, mining engineer of the Bureau of Mines, Birmingham, Ala., and J. J. Corey, Coos Bay, Oregon.

Sub-committee No. 5 will deal with regulations for use of mine-rescue apparatus in metal mines. D. Harrington, mining engineer of the Bureau of Mines, Denver, Colo., will act as chairman. H. J. Rahilly, mining engineer, Anaconda Copper Mining Co., Butte, Mont., will also serve on this committee.

The advisability of standardization of mine-rescue apparatus and methods of use was first suggested by the Hon. William Sloan, Minister of Mines of British Columbia, in a letter to the U. S. Bureau of Mines, dated Sept. 2, 1920, in which he proposed that an international conference be held on the subject. The Bureau of Mines agreed to the desirability of such a conference, with special reference to the methods of use rather than the adoption of any particular apparatus as standard. The conference, at St. Louis, Mo., Sept. 1–3, 1921, was an open one attended by representatives of different governments and departments, representatives from mining companies that carry on training in the use of mine-rescue apparatus, by members of mine-rescue crews and by manufacturers of mine-rescue apparatus. The meetings were presided over by George S. Rice. The following resolution was adopted:

WHEREAS, it is the sense of this conference that it is highly important to advance the art of mine-rescue work by a certain degree of standardization of mine-rescue methods and the use of apparatus and appliances so that improvements may be effected along lines which will guide and assist those engaged or concerned in mine rescue work.

THEREFORE, be it resolved, that a committee be designated by the chairman, at his convenience, that will at some later date or dates as may seem expedient, make a report or reports under the auspices of the Bureau of Mines, which will be made public; and that such committee shall continue its work until such reports have been made or until there shall be a future International Mine-rescue Conference called or held under the auspices of the U. S. Bureau of Mines.

An organization committee met at the Bureau of Mines Experiment Station, Pittsburgh, Pa., Sept. 5–7, and agreed upon the scope of the duties of the various sub-committees.

It is understood that the work of the Mine-rescue Standardization Committee will be carried on largely by correspondence, with occasional meetings as they can be undertaken. All reports are to be submitted to the chairman ex-officio through the secretary, J. W. Paul, United States Bureau of Mines, Pittsburgh, Pa.

# Personal Notes and Biographies

**Anton Gronningsater** is with the British American Nickel Corpn., Ltd., Ottawa, Ont., Canada.

**Leonard G. Donnelly** is with the Maracaibo Oil Exploration Corpn. at 43 Exchange Place, New York.

**H. P. Parrock** is doing special work with the Draper Corpn. at Hopedale, Mass., and is making his home in the East.

**W. W. Wishon** is living in Kingman, Ariz., where he is consulting engineer for the Katherine Big Four Mines Corpn.

**Joseph W. Revere** has retired from active service in the coal fields and is living at his home in Canton, Mass.

**W. C. Page,** formerly mill foreman for the Walker Mining Co. at Portola, Cal., is sales engineer with the Hardinge Co. in Salt Lake City, Utah.

**Mortimer A. Sears** has re-entered Government service as mineral examiner in the General Land Office, Department of the Interior, Washington, D. C.

**David C. Wray,** recently with the Mineral Point Zinc Co. at Depue, Ill., has been with the American Zinc & Chemical Co., at Langeloth, Pa., since Oct. 15.

**Leslie S. Breckon,** recently mine foreman with the Cerro de Pasco Copper Corpn., in Peru, is now superintendent of the Consolidated Mascot Mines Corpn. at Hailey, Idaho.

**L. Avis Billips** has resigned his position as division engineer of the United States Coal & Coke Co. at Lynch, Ky., and has opened an office in Bluefield, W. Va., for consulting work on coal properties.

**P. B. Lord,** recently mine superintendent at the Morenci Branch of the Phelps Dodge Corpn., is at Minas Tecolotes y Anexas, Santa Barbara, Chih., Mexico, as assistant superintendent of the Santa Barbara Unit, American Smelters Securities Co.

**Stanley P. Rockwell,** recently metallurgist with the Whitney Mfg. Co., has opened an office for consulting work, at 65 Highland St., Hartford, Conn. Mr. Rockwell is the inventor of the Rockwell hardness tester, and will specialize on carburizing and case hardening.

**Henry A. Tobelmann,** who has been with the Calument & Arizona Mining Co. since 1906, has resigned to accept a position in New York. Mr. Tobelmann had much to do with the successful development and operation of the New Cornelia process, which has treated nearly 7,000,000 tons of low-grade copper ore at a good profit.

**T. H. Jenks** is recovering slowly, at his home in Los Angeles, from an illness of two months that began with the bite of a poisonous reptile while Mr. Jenks was on a trip into the interior of the West Coast Section of Mexico from Mazatlan. Blood poisoning set in and infection extended throughout his foot and leg up into the groin. Lack of medical attendance in the beginning made matters worse. The first illness was followed by a severe attack of malarial fever, which has kept him in bed until the present time.

## Joseph Warner Edwards

JOSEPH WARNER EDWARDS, whose death occurred on Nov. 7, 1921, at Denver, Colo., was one of the most able of American mining geologists of the passing generation.

Mr. Edwards was born April 23, 1852, at Philadelphia, Pa., the son of the late Edward Bird Edwards and Lydia Ford Edwards. He attended the public schools from 1858 to 1865 and completed his academic course in Switzerland and Germany from 1865 to 1870. He was an ardent student of rocks from early boyhood, and in 1871 chose geology and mining as his life work. He was a special student of geology at the University of Pennsylvania in 1873–4 and was an aide to Persifor Frazer in the Second Geological Survey of Pennsylvania from 1874 to 1876.

He completed a scientific course at the Royal Saxon Academy of Mines at Freiberg from 1876 to 1879 and at Heidelberg, in 1880–81, took high honors in geology, mineralogy and allied subjects. Then he entered the field of active operations in the three Americas.

He became a member of the American Institute of Mining Engineers in 1876 and was an active member in the early formative days of the Institute; always intensely interested in its proceedings and loyal to its inspirations. He was also a member of the Academy of Natural Sciences of Philadelphia, the Engineers' Club of Phila., the American Association for the Advancement of Science, the Mineralogical Society of America, the Colorado Scientific Society, the National Geographical Society, the Franklin Institute and others. He was always ready to join any group of men in the advancement of scientific research or investigation. His life work was woven into the pioneer mining history of Colorado and the West.

He was a man of high culture, keen analytical mind and gracious personality. His fine attainments as an accomplished and upright scientist, his genial generous

Digitized by Google

character and his loyal friendship are a heritage and an influence that will live long in the memory of his many friends and associates. He belongs to that early group of scientists whose aspirations and labors have done so much to formulate and adyance the practice of the profession of mining engineering and to maintain its high ethical standards.

WAYNE DARLINGTON.

## John Elmer Jones

JOHN ELMER JONES was born Dec. 9, 1870, at Summit Hill, Carbon Co., Pa., the son of Thomas D. and Ruth Bynon Jones. He was a student at Mt. Pleasant Military Academy from 1884 to 1888; at Lehigh University from 1888 to 1890; and at Columbia University from 1890 to 1893. He received the degree of mining engineer from Columbia.

He entered the employ of the Mill Creek Coal Co. in 1893, and remained with that company for twenty-eight years. He was assistant superintendent until, in 1917, he succeeded his father in the position of general manager and vice-president. He was on the board of directors of the Vinton Colliery Co., and also of the Hazleton National Bank.

On Feb. 13, 1921, he died very suddenly at his home in Hazleton, Pa., after an illness of only three weeks. His wife, who was Louise Alice Dryfoos before her marriage, died in 1908. One daughter, Ruth, his mother and one sister survive him.

## James S. Cunningham

JAMES S. CUNNINGHAM, well known coal man, died at Saint Francis hospital in Charleston, West Va., on Dec. 12. His death resulted from an accident that occurred as Colonel Cunningham was entering his home by the rear door, after having placed his automobile in the garage. His arms were loaded with Christmas packages and as he stepped upon the top step, his foot slipped and he fell backward, striking his head on the cement walk below. His injuries were found to be so serious that he was taken to the hospital at once for an operation that it was hoped would remove a blood clot that had formed on the brain. His skull was found to be badly fractured on the left side and the operation failed to save his life.

Colonel Cunningham had been a resident of Charleston since 1902. He was personal consulting engineer for E. J. Berwind of New York, the president of the Bengal Coal Co.; general manager of the Kentland Coal and Coke Co. and director and personally interested in a number of other coal companies in West Virginia and eastern Kentucky. He was a director of the Union Trust Co. and of the Y. M. C. A. of Charleston and actively interested in charitable movements. He was rated as one of the foremost experts of the country in coal formation and production.

Colonel Cunningham was of rugged Scotch ancestry and was born in Eckley, Luzerne County, Pa., Sept. 7, 1856. After graduation from Lehigh University in 1879, he was mechanical engineer for the Lehigh and Susquehanna Coal Co., then general manager of the Midvale Ore Co. For the past 32 years he was consulting engineer and geologist for the Berwind interests.

He was a thirty-second degree Mason, a Shriner, life member of the Elks, member of the American Institute of Mining and Metallurgical Engineers, Rotary Club and various local organizations and clubs in the East. He was a member of the Presbyterian church.

His widow and three children survive him. A daughter, Mrs. Worth Clark, resides at Atlantic City, N. J., and two sons, Walter H. and Roy H., live at Huntington. A number of brothers and sisters reside at Allentown and Scranton, Pa.

## Robert L. Ahles

ROBERT LAWRENCE AHLES, president, treasurer and general manager of the Sweet's Steel Co. of Williamsport, Pa., died on Oct. 16, 1921, at Westbury, Long Island. The following quotation is from the Resolutions adopted by the directors of the Sweet's Steel Co. a few days after his death.

> Mr. Ahles came to this city in 1907 and took charge of this company's affairs, and through all its history since that time he has been a dominant and leading figure. Through days of adversity and prosperity he stood unflinchingly in his place. He was always loyal to his company and to his associates. He treated everyone with whom he came in contact with openess, frankness and the utmost fairness. He extended a helping and willing hand to all his employees, from the humblest workman to the highest executive officer. Through good report and evil report he was always the same; steadfast, calm, persevering and onward pressing. We, his associates do record our recognition of his keen intellect, his grasp of general conditions, his business foresight and, above and beyond all, his human kindness and his regard for his fellow man.
>
> We desire to testify to his exceptional interest in the welfare of his employees; his care for their well being; his solicitude for their general welfare; his readiness to assist them in all their personal and private difficulties and to aid them in the struggle of life.

Mr. Ahles was born at Bayside, N. Y., Aug. 14, 1876. His education was gained in military and technical schools. By profession he was a mining engineer and gained practical experience in some of the largest iron and steel concerns in the country.

He was a director of the Trust Company of New Jersey, Hoboken, and of the West Branch National Bank of Williamsport; a member of the Engineers' Union, St. Nicholas, Tennis and Racquet, and other clubs in New York City and of the Ross Club of Williamsport. He was a member of the Sons of the Revolution and of the Cercle Francais, Paris. His technical societies were the American Institute of

Digitized by Google

Mining and Metallurgical Engineers, which he joined in 1902, and the American Iron and Steel Institute.

Mr. Ahles served in the navy in the Spanish-American War. He made repeated application for admission to active service after the United States entered the World War, but was refused. He served as a captain in the Red Cross service, in charge of several large hospitals in France and Belgium.

While Mr. Ahles regarded Williamsport as his home, he had a beautiful country estate at Westbury, L. I. He left his wife, Mrs. Helen Kemper Ahles, and one daughter.

## E. A. Miller

ELTON A. MILLER was killed on June 30, 1921, by falling rock. Mr. Miller was mine superintendent for the Saline Coal Co., at Harrisburg, Ill., and was on a tour of inspection through the mine when the accident happened.

"Kelly" Miller, as he was known to his college mates and intimate friends, was one of the most popular men of his college, Missouri School of Mines at Rolla. He was an athlete, and was a four M man in football. He was a member of the Grubstaker Club and Quo Vadis, and was president of his class in his sophomore year. Mr. Miller married Miss Florence Ary, who, with three children, survives him. While in Rolla he joined Rolla Lodge of Masons, and his body was laid to rest in Edwardsville, Ill., according to the ancient rites of Free Masonry, at the request of the Rolla Lodge.

## Necrology

THE deaths of the following members were reported to the Secretary's office during the month Nov. 15, to Dec. 17, 1921.

| Date of Election | Name | Date of Death |
|---|---|---|
| 1883 | Cunningham, James S. | Dec. 12, 1921 |
| 1911 | Dunstan, Simon P. | Aug. 30, 1920 |
| 1876 | Edwards, J. Warner | Nov. 7, 1921 |
| 1911 | Engel, George W. | March 25, 1920 |
| 1889 | Hancock, Strangman | Oct. 29, 1921 |
| 1920 | Hawkins, William P. | Nov. 23, 1921 |
| 1921 | Wolf, Victor Laurence | Sept. 10, 1921 |
| 1900 | Osgood, Samuel W. | Oct. 4, 1921 |

## Names of Men and of Things

IT IS not often that the name of an individual is added to the world's vocabulary of common nouns but the *New York Times* directs attention to four names that are well known in the field of electricity. The name of the French physicist and mathematician, Ampere, identifies a current of electricity produced by a unit of force which bears the slightly modified name of an Italian electrician (Volta), passing through the resistance of a unit known by the name of a German electrician (Ohm), or which produces a unit of power that bears the name of a Scottish inventor (Watt).

"Despite the fact that a hundred years have passed since Ampere made his great discoveries," says the *Times*, "he is remembered by a republic that is not ungrateful. With all her taxation and privation at home and anxieties abroad, France takes thought of her great citizens of the mind. The whole earth, around which encircling currents run with its daily revolution, as Ampere discovered, has good reason to use an 'ampere hour' with France, in grateful memory of him."

## Coming Meetings of Societies

| Organization | Place | Date |
|---|---|---|
| Soc. Automotive Engrs. | New York, N. Y. | Jan. 11–12 |
| **Amer. Inst. Min. & Met. Engrs.** | **New York, N. Y.** | **Feb. 20–23** |
| Amer. Ceramic Soc. | St. Louis, Mo. | Feb. 27–Mch. 2 |
| Amer. Soc. Mech. Engrs. | Atlanta, Ga. | May 8–11 |
| Foreign Trade Convention | Philadelphia, Pa. | May 10–12 |

## Winter Mining Session in Seattle

THE 26th annual winter mining session of the College of Mines, University of Washington, will be held during the 12 weeks from Jan. 5 to March 22. This session is open to any man who can read and write English. The expense will be limited to a tuition fee of $15, laboratory deposits to cover materials actually used and the cost of the necessary text books. The training consists of lectures with laboratory practice.

## Radium*

FOR many years radium was exclusively produced from the Austrian ores at Joachimsthal; later, it was obtained from pitchblende deposits in Cornwall, and from autunite deposits in Portugal. About nine years ago, officials of the Bureau of Mines found that the carnotite deposits in southwestern Colorado and eastern Utah represented the largest bodies of radium-bearing ore in the world.

At the present time, the United States produces much more radium than all the rest of the world together. From the beginning of the industry in 1913 to January, 1921, approximately 115 gm. of radium element were produced in this country. Probably not more than 40 gm. have been recovered from foreign ores since the discovery of radium by Madame Curie.

# Correspondence and Discussion

## Copper at Retail

IN CONNECTION with the efforts of the copper and zinc producers to increase the use of their metals in domestic consumption, there has been discussion of the prices asked at retail for common articles of copper and brass.

Recently I had occasion to buy 2 doz. ordinary brass screws in the largest hardware shop of a city of 40,000 population. The price was 60 cents for the lot.

"That's a pretty stiff price," I remarked to the salesman.

"Well, you know, the raw materials are mighty dear," he replied, patronizingly, and perhaps with an idea of comforting me.

When I arrived home I weighed the lot on an accurate balance and got a reading of 0.2 lb., from which I computed brass in ordinary wood screws at retail at $3 per lb. The raw materials at recent prices come to about 10 c. per lb. Add a cent for brass-making and then a little for the two simple processes of drawing rods and cutting screws.

I am aware that the retail hardware merchant makes only two turnovers of his stock annually, of his high cost of selling, etc., but with all due allowances for those conditions $3 per lb. for copper screws looks like a discourager of consumption. I should not draw deductions from a solitary and trifling incident, but I think I should like to ascertain if there be any stoppage of the pipes leading to consumption through these agencies.

W. R. INGALLS.

New York, Nov. 20, 1921.

## The Physics of Steel

IN HIS letter of Oct. 6, Mr. John Orth Liebig has opened up again the old question of how near the steel mills should be expected to work to both the chemical requirements and physical tests called for in our standard specifications, without cutting down their output to an unreasonable extent.

He, no doubt, has found some mills that can give him much better and more uniform steel both chemically and physically than others. A careful investigation of the different methods in use at these mills will give him a very fair answer to his question. I would suggest that, after doing this, he give us the results of the investigation at the February meeting of the Institute, as at that time our new discussion on The Physics of Steel will be opened by the presentation of the writer's paper, with several others.

Mr. Liebig has also referred to the heat treatment of alloy steels in rolling and asked some questions regarding same. The writer did not consider these steels at all in his paper, but only refers to the ordinary structural carbon steels.

Alloy steels have come into such general use since our former discussions that they will be given a great deal of attention in our new discussions. The former suggested lines on the discussions of the Physics of Steel will be brought up to date and include the important advances in metallurgy of steel since 1893. Any suggestions that Mr. Liebig can give us for this work on the steels he has referred to will be appreciated.

For convenience of comparison with other steels, it would be well to give the chemical composition of the steels he refers to in addition to the code number of the Society of Automotive Engineers.

For convenience of reference the following extract from Circular No. 3, of 1893, as printed in Volume 24 of the TRANSACTIONS, is here given:

THE PHYSICS OF STEEL

The following lines of discussion are suggested, but are not in any way exclusive.

I. Correspondence between chemical composition and fracture, microstructure and physical properties.

II. Influence of—
- (1) Casting temperature
- (2) Manner and temperature of heating
  - (a) For rolling
  - (b) For annealing
- (3) Work
- (4) Finishing temperature
- (5) Rate and mode for cooling
  - (a) After forging
  - (b) For casting

on
- (a) Fracture.
- (b) Microstructure.
- (c) Physical properties
- (d) Tensile properties
- (e) Residual stress

III. Segregation as affected by—
- (1) Composition
- (2) Casting temperature
- (3) Rate of cooling

IV. Blow-holes and pipes; their volume and position as affected by—
- (1) Composition
- (2) Casting temperature
- (3) Casting pressure
- (4) Rate of cooling
- (5) Special additions
- (6) Forging

V. Hardening: relation between tensile properties and hardness of quenched steel, and—
- (1) Quenching temperature
- (2) Quenching medium
- (3) Size of piece quenched

## New Features in Structural Geology of the Anthracite Basins*

By James F. Kemp, New York, N. Y.

IN EARLIER years, the custom prevailed of regarding the anthracite basins as cases of folding with slight development of faulting. Folding is so pronounced and, in the eastern and western middle fields, at times so violent, that the inference was a natural one and led to the widespread impression that practically all the disturbances of the seams could be explained in this way. The cross-sections and maps prepared forty or more years ago for the Second Geological Survey of Pennsylvania, by Mr. Ashburner under Prof. J. P. Lesley, exhibit little else than folds.[1] So far as I can discover, faults fail in the charts, except in one small case in the Henry Colliery near Plainsville on the outskirts of Wilkes-Barre.

Several years ago, while spending a day or two in Wilkes-Barre, under the guidance of R. V. Norris, I looked over some recent and accurate cross-sections of a number of the large collieries and was deeply impressed with the peculiar behavior of some of the seams and the intervening shales. Thus, a seam might present a small, more or less overturned fold, rising 30 to 50 ft. above its general course, and yet the movement would be taken up in the overlying shales, so as hardly to be noticeable in the seams next above or below. These and similar anomalies, especially when shown with the accuracy of engineer's surveys, possessed great scientific and practical interest, bearing, as they do, not alone on coal mining, but on theoretical geology and the actual behavior of strata under great compressive stresses. In preparation for the semi-centennial meeting of the Institute, an effort was made to secure some of interesting sections for presentation. The collection shown was mainly due to Douglas Bunting of the local committee.

The illustrations are taken from all four of the main basins, but are chiefly from the portions nearest Wilkes-Barre. The first are in the southern part of the Northern, or Wyoming, Basin. The general geological section is as follows:

| | Anthracite Region | Western Pennsylvania |
|---|---|---|
| *Permian*..... | | Dunkard or Upper Barren Series |
| *Pennsylvanian* or *Carboniferous*..... | *Coal Measures* thickest in southern or Schuylkill Basin with about 20 coal seams. *Pottsville* Conglomerate, thickest in Schuylkill basin, with 6 coal seams. | *Monongahela* or Upper Productive Series, 6 coal seams. *Conemaugh* or Lower Barren series. *Allegheny* or Lower Productive series, 7 coal seams. *Pottsville* Conglomerate. |
| *Mississippian* or *Lower Carboniferous*... | *Mauch Chunk* red shales. *Pocono* sandstone. | *Mauch Chunk* red shales containing also the *Mauch Chunk* limestone. *Pocono* sandstone. |

The subdivisions of western Pennsylvania cannot be easily carried out in the anthracite basins, and correlation of the strata must be made chiefly by comparative study of the fossil floras of the seams, as has been in progress by Dr. David White. A stratigraphic feature of much importance relates to the present, or former more extensive, existence of Permian strata in the anthracite areas, because on this question and the determination of the section that has been removed by erosion, depends the amount of load carried by the anthracite coal measures when they were folded. The folds and overthrust faults are characteristic of relatively small load. Moreover, individual small folds often become larger and larger as we approach the surface from the deep workings, just as if, with diminution of load more extensive movements and adjustments became possible.

The northern, or Wyoming field, on the whole, is the least violently folded of the four main fields. The sections, however, make apparent that it has suffered from severe compression and that the easing of the strain has at times involved thrust faulting of great extent. An increased thickness of the geological section, together with sharply compressed, deep synclines, characterizes the southern field.

In the oral presentation of this paper, additional sections were shown as greater latitude was possible with lantern slides than is the case with the engraved figures. But the ones reproduced serve to bring out the main features. The existence of thrust faults

*Wilkes-Barre Meeting, September, 1921.

[1] There are several volumes on the Anthracite areas, listed as A-2 and A. A. The maps and cross-sections are folded in accompanying pockets, but also are to be found unfolded in the portfolios of the Grand Atlas, Division II, Parts 1 and 2.

Digitized by Google

of a displacement to be measured on the dip of as much as 1000 ft. is the most important structural feature brought out. The tightly compressed and stretched folds, although more generally familiar, can never fail to be an object of interesting study to the geologist concerned with mountain-making processes. Where they can be illustrated from the engineers' surveys of the mines, they have an exact quantitative character of extreme value to the investigator. Some of the features commented upon cannot fail to suggest the conclusion that the anthracite measures did not rest under a great load when they were folded, but that they were fairly free to break and slip by, when strained beyond a moderate ability to resist.

## Storage-battery Locomotive as Applied to Mine Haulage*

By Charles E. Stuart, New York, N. Y.

A THOROUGH visualization of the subject would contemplate a comparative analysis of haulage machines and batteries of various types; the relationship of the storage-battery locomotive to other types of mine haulage should be considered and limiting factors in each case should be carefully developed. This paper will briefly deal with these factors.

About 1913, several large manufacturers sought to produce a reliable storage-battery locomotive. For two or three years, although a satisfactory battery and thoroughly substantial mechanical parts and motors were available, the development was slow, because of the failure of the manufacturers' thoroughly to understand mine requirements.

The interest of the mine owner in haulage is concerned solely in the number of tons of coal or ore that he can safely haul in a day and the cost per ton of this work.

In the coal mines having the lowest haulage costs there will be found: Entry trackage of not less than 40 lb. weight, well supported and well maintained on ties; room rails of 20 lb.; cars of the greatest cubical content permitted by the height of the seam (in low seams) or (in high seams) by the ease of loading. In well-managed soft-coal mines where the shovel is used, cars with a cubical content of 235 cu. ft. are found. The track gage is not less than 36 in. and usually is over 40 in. The trips contain from 25 to 50 cars and the main haulage locomotives are from 10 to 30 tons. There is double track on the main headings, good voltage at the working centers, the gathering locomotives are from 4 to 6 tons, and the workings are concentrated.

Within the car limits indicated, with a concentration of work, general grades not exceeding 6 per cent., the work for the storage-battery locomotive is collecting the cars from a number of places or rooms and taking them to a sliding where the trip is made up for the heavy locomotives.

Under these conditions, the storage-battery locomotive containing motors and batteries of ample capacity for the actual cycle of duty has the following advantages:

1. It is unnecessary to string trolley wire and bond tracks away from the main haulage ways.

The above in its relationship is practically characteristic of mine haulage in general.
Similar tests several weeks later after power and other conditions had been improved, indicated a 100% increase in productive effort and proportional decrease in equipment needed for work produced, power consumption and other incidental costs.
This chart represents one step in a test carried from boiler to face of coal
A = Possible work under prevailing conditions.
B = Possible work under conditions which might have prevailed

Graphic analysis of daily performance of locomotives.

2. In thin coal, it is unnecessary to brush; that is to take up bottom in order to make height necessary for mules.

3. No time is lost by making cable connections with the trolley on entering rooms, nor by cutting the reel cable and splicing it where cut.

4. The chance of personal contact with the trolley wire is absent.

5. In a gassy mine, away from the well-ventilated headings, the absence of a spark at the wheel or the trolley may be a vital consideration. In those mines where safety lamps are required, it is only a matter of time before the use of the trolley and reel locomotive for gathering will be prohibited. The storage-battery locomotive can be, and is being, made gas-proof and will pass the tests of the U. S. Bureau of Mines.

6. The speed and haulage capacity of the machine measured in pounds drawbar pull, will enable it to displace a number of mules and drivers and should materially lower the cost of gathering.

7. An invaluable consideration is the independence of the storage-battery locomotive with respect to either substation or power plant during idle days. At such times a storage-battery locomotive may be used for handling supplies or for other purposes.

*New York Meeting, February, 1922.

Digitized by Google

The writer is now working on plans for a mine in which alternating current will be used for all stationary motor drives and for mining machines. For a short time, animal haulage will be the cheapest; but when the economic limit for this haulage is reached, it is proposed to purchase a charging set and storage-battery locomotives. In many cases, with a small mine, the storage-battery locomotive will be the most economical haulage unit for the life of the mine. With larger development, the third step would be the introduction of the heavy type of locomotive and the diversion of the storage-battery locomotive to gathering.

### Conclusions

To sum up, the storage-battery locomotive is proving a complete success and a means for reducing costs as well as risk of accident, where properly applied. Its failure at any mine will be accounted for by one of the following:

1. A duty cycle in excess of battery capacity; this has been the most frequent cause for failure.
2. Misapplication is a common error; that is, the effort to use the storage-battery locomotive where mule power is cheaper or where man power in conjunction with the strictly haulage type of locomotive would be cheaper.
3. Failure to select a locomotive that will stand the abuse of mine practice.
4. Failure to provide a reasonable amount of care and attention.

---

## Malleableizing of White Cast Iron*

By Arthur Phillips, New Haven, Conn., and E. S. Davenport, Naugatuck, Conn.

THE purpose of this paper is to present certain data and observations resulting from a series of experiments dealing with the heat treatment and microstructure of commercial white cast iron and its derivative, malleable iron. A review of the literature leads to the belief that many data of a fragmentary character treating of the graphitization of white cast iron have been of little value, mainly because of the diversity in chemical composition of the materials employed in the tests. Moreover, when feasible, annealing periods at least comparable to those of current practice have been adopted.

In this paper the following subjects are discussed: Data on the thermal critical points of white cast iron and malleable iron; changes produced in tensile properties and microstructure of white cast iron by annealing at different temperatures within the range 760° to 1100° C.; relation of thickness of wall section of hard iron to microstructure and tensile properties of malleable iron obtained under normal annealing conditions. Notes on mechanics of graphitization of normal white cast iron as observed in specimens quenched after various periods of anneal at approximately 800° C.

The American "malleableizing" process consists essentially of a lengthy heat treatment at a moderately high temperature, followed by extremely slow cooling, with the object of converting the cementite of the white cast iron into graphite, or "temper" carbon, and ferrite. From the physicochemical point of view, the changes involved during this treatment are extremely complicated and are not thoroughly understood at the present time.

The exact temperature at which temper-carbon begins to form has been greatly disputed. This point is discussed in this paper and some experimental results bearing on the subject are offered.

The literature records the results of a number of investigators who have determined the critical temperatures of cast iron covering a wide range of composition; what seem to be the most significant and valuable data available are summarized in a table.

This series of experiments to determine changes produced in mechanical properties and microstructure of white cast iron by annealing at different temperatures within the range 760°–1100° C. was begun primarily to determine the effect of variation in temperature, of the order commonly found in commercial annealing furnaces, on the structure and tensile properties of the completely malleableized product.

The study of the microstructure of the bars tested leads to the following conclusions:

1. The ferrite grain size increases with the temperature and, probably, with the time of anneal.
2. The temper-carbon areas produced at the lower temperatures are more compact and sharply outlined than the graphitic areas obtained at the higher temperatures. High-temperature temper-carbon is, in general, characterized by a more or less porous structure of ragged and "spidery" outline. The higher temperatures have a disintegrating effect on the compact and rounded masses characteristic of carbon precipitated at the lower temperatures.

The manufacturer is interested in the effect of the rate of cooling of the hard casting on the mechanical properties of the malleable casting subsequently obtained (assuming constant chemical composition). Specimens were packed in sand and annealed and the resulting structure is shown in figures.

A comparison of the hard-iron structures and the corresponding malleable structures indicates that (1) the finer the hard-iron structures, the finer will be the ferrite grain and temper-carbon areas of the malleable iron; (2) the effect of the wall thickness, and therefore the rate of cooling of the white cast iron, is more pronounced in the case of the temper-carbon areas than in the case of the ferrite.

Although no tensile data were obtained in this experiment, direct comparison of the structures described with those corresponding to known tensile

*New York Meeting, February, 1922.

Digitized by Google

properties leads to the conclusion that variations in wall section cause more pronounced variations in mechanical properties than can be attributed to the thermal gradient incidental to ordinary mill anneal. Doubtless poor mechanical properties are often obtained due to the additive effect of a very high annealing temperature and a heavy wall section.

Briefly stated, the completely cooled normal white iron consists of pearlite and cementite. There are, however, four kinds (from the viewpoint of origin and state of aggregation) of cementite, namely: massive pro-eutectic cementite, eutectic cementite, pro-eutectoid cementite, eutectoid cementite (pearlite).

In some instances, it is possible to distinguish all of these elements within a rather limited area; more often, however, we are unable to make these deductions with any degree of assurance.

Much has been written on the general subject of the graphitization of gray and malleable iron. The earlier investigators in this field apparently believed that it is essentially the structurally free and metastable cementite that decomposes at the higher temperatures to form ferrite and graphite, or temper carbon. More recently, however, several investigators, notably Storey, Archer, and Merica, have suggested the possibility of graphitization direct from solid solution. The writers have been of this opinion for some time and submit micrographs that, although not necessarily conclusive on this point, tend to indicate that under ordinary treatment of white cast iron temper-carbon is formed directly from the solid-solution areas and not, in general, from the massive cementite areas.

In these, and other observations made by us, the temper-carbon in quenched specimens seems to be coincident with the appearance of troostite or martensite. This would seem to signify that no appreciable amount of temper-carbon is precipitated until a saturated solution is formed.

As the time of anneal increases, the size and number of the temper-carbon areas increase, as might be expected. Although it is impossible to make any positive statement regarding the structural element giving birth to temper-carbon during the early stages of graphitization, we believe that in certain quenched samples, the temper-carbon was first precipitated in appreciable amounts in the solid-solution areas and not, in general, in the patches of massive cementite. As additional evidence there are inc uded four micrographs of specimens, one quenched after 21 hr. at 780° C. and the other quenched after 20 hr. at 800° C.

It is not unlikely that slight fluctuations in temperature during the effective annealing period may play an important part in the formation of temper-carbon. After the austenite has become saturated with carbon, whether it is in the form of cementite or as atomic carbon, a slight drop in the temperature would render the austenite supersaturated at the lower temperature and carbon would be rejected, apparently as temper-carbon. As temper-carbon is less soluble than cementite in gamma iron, when the temperature rises the austenite would become saturated at the expense of the structurally free cementite. Thus alternate precipitation and saturation takes place throughout the anneal; moreover, further separation of temper-carbon takes place during the slow cooling following the anneal since the solubility of carbon in austenite decreases with falling temperature. In properly annealed malleable castings little combined carbon can be found, either analytically or micrographically, and we are inclined to believe that the iron-graphite eutectoid is at approximately zero per cent. carbon.

---

## Acid Open-hearth Process for Manufacture of Gun Steels and Fine Steels*

By W. P. Barba and H. M. Howe

WHEN this country went into the war, two concerns only, the Bethlehem Steel Co. and the Midvale Steel and Ordnance Co., knew how to make steel fit for great cannons, and at these concerns there were relatively few men who knew the whole art. Fortunately, certain of these men put their knowledge at the service of the Government, and proceeded to instruct the metallurgists at the arsenals and at various steel works.

At this time there were serious difficulties in the manufacture, for the Government, of aircraft and high-speed engine crankshafts, of certain ordnance forgings, and of shells for both the Army and Navy. There were indications that the source of some of the difficulties was the melting of the steel and the production of the ingot. Hence, steel melting and ingot production were first studied, in order to guide the wartime manufacturers to an even larger percentage of useful production from the steel initially melted.

Sections 1 to 11, inclusive, of the paper give a condensed statement of the subject, in particular indicating the chief ends to be held in view in conducting the open-hearth process for gun steel, while in the remainder of the paper, to and including section 58, these matters are elaborated.

1. *Composition.* In order to comply with the physical tests of American ordnance specifications, the composition of nickel-steel pieces for cannon and shafting should lie within the following limits, the exact composition varying with the part of the gun which the piece in question is to form, whether tube, jacket, hoop, or other.

| | Per Cent. |
|---|---|
| Carbon | 0.35 to 0.50 |
| Phosphorus | below 0.05 |
| Sulfur | below 0.05 |
| Manganese | 0.50 to 0.75 |
| Silicon | 0.15 to 0.30 |
| Nickel | 2.50 to 3.75 |

*New York Meeting, February, 1922

Digitized by Google

For ease of exposition we have assumed a specific carbon content, 0.35 per cent.

The steel should be brought at the moment of teeming to the desired composition in every respect. (Throughout this paper tapping refers to pouring the steel from the furnace into the ladle, and teeming or pouring to pouring it from the ladle into the mold.)

(*a*) The manganese and silicon must be brought to the desired proportion. In order to do this, the bath should be freed from oxygen as nearly as possible and certainly to a constant degree. This freedom from oxygen is important also for lessening or preventing segregation, blowholes, and structural metallurgical weakness.

(*b*) Phosphorus and sulfur must be below the prescribed limit, and to this end the stock must be sufficiently free from them.

(*c*) The chromium and nickel must be within the prescribed limits.

2. *Temperature* must be accurately regulated, for reasons which appear in the following paragraphs.

3. *Segregation* must be restrained, and to that end the steel must be poured at a relatively low temperature and must be free from oxygen. (This represents American practice. In section 39, are considered the reasons that favor the opposite course of pouring at a high temperature, as is done in Continental Europe.)

4. *Columnar crystallization* must be restrained and the size of the dendrites kept down. To this end the teeming temperature should be relatively low.

5. *Piping* must be restrained. To this end, the ingots should be cast with the large end up, and at as low a temperature and as rapid a rate as the ingot sizes and the chemistry of the steel permit.

6. *External cracking* should be prevented. Here we may note that there are two periods of brittleness: First, when the steel is cooling toward the solidus, and thus is a viscous solid, an intimate mixture of a large proportion of already solid pasty particles and a relatively small proportion of still molten steel. Second, at the blue heat. The tendency in any given layer to crack in this period is often exaggerated by the simultaneous expansion which the deeper seated and slightly hotter layers are undergoing in passing through the recalescence.

We guard against this external cracking:

(*a*) By tapering the mold so strongly that the ingot frees itself from it readily during the contraction period immediately after pouring, and hence is readily withdrawn.

(*b*) By pouring at a relatively low temperature and slowly first, so that as the molten steel rises in the mold, the thickness of the already solidified walls may increase fast enough to withstand the increasing ferrostatic pressure, and second, that the size of the columnar crystals and the dendrites may be restrained.

(*c*) By fluting or otherwise shaping the outer surface of the ingot, which has little power of stretching, so that it can bend horizontally and thus accommodate itself to the resistance of the slower cooling and hence slower contracting interior.

7. *Internal Cracks Including Flakes* must be restrained: (*a*) By interrupting the relatively rapid cooling in the mold and replacing it with slower cooling in ashes as soon as the ingot has solidified sufficiently to be moved without danger of cracking. When the ingots are cast with the small end up, their molds may be stripped before they have cooled far enough to make it expedient to bury them in ashes. If this is done, the time between stripping and burying them forms a third portion of cooling.

(*b*) By saddening and thereby toughening the ingot very carefully, so as to prevent cracking it mechanically in forging or rolling. (To *sadden* an ingot means to substitute strong cohesion and toughness for its initial fragility, due to its having a very coarse crystalline sugar-like structure. This may be done by giving it a succession of light reductions under a hammer or press, or in a rolling mill. Sadden is evidently closely related to sodden.)

(*c*) By retarding the heating of the ingot for forging and that of the forgings themselves, so as to lessen the thermal stresses.

(*d*) By as great freedom from inclusions as possible.

8. *Retention of Inclusions* must be restrained. (*a*) By deoxidizing the molten steel as fully as possible by means of the carbon of the pig iron, because the product of its oxidation is gaseous and escapes, whereas those of all other deoxidizing agents are solid or molten and tend to remain as inclusions. In order that as much as possible of the deoxidation should be done by carbon, the working temperature during refining must be held as high as the safety of the roof will permit.

(*b*) The nearly complete deoxidation by carbon should be followed by further deoxidation by silicon. The manganese should not be added till after this silicon has done its work of deoxidation, in order that as little as possible of it may oxidize. This is both so that the manganese content of the product may be as nearly constant as possible, and that as little manganese oxide as possible may form to corrode the siliceous hearth of the furnace and form inclusions of manganese silicate with the silica so eaten away. This postponement clearly tends to lessen the oxidation of manganese; first, by shortening its stay in the furnace, and, second, by pre-oxidizing the bath with the silicon.

(*c*) The steel should be held in the ladle a moderate length of time to allow the inclusions to rise to the surface, and also for the much more important purpose of permitting the finished steel to fall to the proper temperature for casting into a successful ingot.

9. *Hot and Cool Pouring.* American practice, which is the chief subject of this paper, may be summed up briefly as Refining Hot but Pouring Cool. We have now seen four reasons for cool pouring:

Digitized by Google

1. That it is thought to restrain segregation;
2. That it restrains the size of the dendrites;
3. That it lessens piping;
4. That it lessens or prevents external cracking.

On the other hand, it certainly favors the retention of inclusions, by shortening the time available for their rising to the surface in the ladle. Their opportunity to rise is really good only so long as the steel is completely molten. As soon as it cools to the liquidus, it ceases to be wholly molten and becomes an emulsion of an ever-increasing quantity of pasty particles of metal which have already solidified.

10. *The Furnace* must be protected. To the end,

(*a*) Its hearth should be protected from iron oxide by covering it, before charging the scrap, with about half of the pig iron used.

(*b*) The working temperature of the furnace must be maintained during the melting and refining periods at the highest point consistent with safety to the furnace: first, so as to shorten the melting period, during which the hearth is exposed to the attack of the iron oxide, because it is not fully covered by the molten charge; second, so as to stimulate the deoxidizing action of the carbon of the bath during the refining period.

11. *Recapitulation.* There are really only four purposes served by these various precautions, with their many sub-precautions, viz.: To make the ingots: (*a*) of proper and uniform composition; (*b*) of proper macro- and micro-structure; (*c*) sound, that is free from pipes, blowholes, cracks and roughness; (*d*) to prolong the life of the furnace.

---

## Effect of Time in Reheating Quenched Medium-carbon Steel Below the Critical Range*

By Carle R. Hayward, Daniel M. MacNeil and Raymond L Presbrey, Cambridge, Mass.

At THE February, 1916, meeting of the Institute, a paper presented by Hayward and Raymond gave the results of a study on the effect of time in tempering medium-carbon steel, when the following conclusions were reached:

It is not fair to consider the question settled when only three specimens were used for each treatment, but the results obtained indicate that for reheating quenched medium-carbon steel to temperatures below 500° it is only necessary to heat it through. Longer heating has little or no effect on the tensile strength, ductility, or hardness. At temperatures above 500°, increasing the time of treatment causes a slight falling off in hardness and tensile strength with a corresponding increase in ductility.

In the discussion of the paper these conclusions were attacked and evidence presented that seemed to throw doubt on their accuracy. The authors, however, showed that this evidence was based on high-carbon or alloy steels and no facts regarding medium-carbon steel were presented.

* New York Meeting, February, 1922.

During this study the heat treatment was carried out in a small electric resistance furnace. It held nine specimens, but when these were placed in the furnace the temperature was lowered to such an extent that 30 to 40 min. were required to reach the desired heat. The authors pointed to this as a weak point in the investigation and it seemed wise to supplement the research by work on similar steel but using a different method of heating. This has been done and the results are given in the present paper.

The steel used in this investigation came in three bars ¾ in. in diameter; their analyses are as follows:

| Bar Number | Carbon, Per Cent. | Manganese, Per Cent. | Phosphorus, Per Cent. | Sulfur, Per Cent. |
|---|---|---|---|---|
| 1 | 0.46 | 0.56 | 0.010 | 0.055 |
| 2 | 0.44 | 0.58 | 0.007 | 0.042 |
| 3 | 0.48 | 0.58 | 0.007 | 0.048 |

The specimens were quenched at 850° C. and then reheated in lots of three for 5, 15, 30 min., 1, 2, and 4 hr. at 300°, 400°, 500°, and 600° C. Three specimens cooled in the furnace from 850° C. and three were tested in the quenched condition.

The bars were cut into 5½-in. lengths and heated in a No. 1 Oven furnace made by the American Gas Furnace Co. The furnace was heated to 900° C. and one hird of the specimens introduced on an asbestos board that was supported 2 in. above the bottom of the furnace. This lowered the temperature to about 800°, but after 20 min. it rose to 850°, at which point it was held for 10 min. Then the asbestos board was removed and the specimens quickly dumped into a tank of water. This operation was repeated until all but three of the specimens were quenched; these were allowed to cool in the furnace.

The quenched specimens were reheated, in lots of three, by immersing in a gas-heated pot containing about 75 lb. of type metal. The introduction of the specimens caused no appreciable change in the temperature of the metal and a constant temperature was easily maintained. The three specimens were fastened to an iron rod, to hold them below the surface of the metal and to facilitate their removal. After reheating for the desired time, the specimens were removed from the pot and quickly plunged into water.

In spite of the fact that great care was taken to secure uniform treatment of the three specimens in each set, some sets show erratic results. In four cases, the results were obviously low, so the figures were rejected. In all other cases the average of the three results was plotted in curves. The following points may be properly emphasized:

1. Even 5 min. heating of the quenched steel at 300° C. lowers considerably the strength and hardness and increases the ductility.

2. There is a marked increase in ductility in passing from the 400° to the 500° treatment without an equivalent lowering of strength; it is accompanied, however, by a change from an indefinite to a definite yield point.

Digitized by Google

This was clear on the original load-elongation curves. Although the annealed specimens from the three bars showed the same yield point and ultimate strength, there was a difference in the ductility.

3. The specimens reheated to 600° C. are nearly as ductile as the annealed specimens, but they have an elastic limit about 60 per cent. greater.

4. In spite of several irregularities in the curves it is evident that reheating the steel for 1 hr. is all that is necessary and there are indications that for temperatures of 400° and below, ½ hr. is sufficient.

## Time to Pay Out as a Basis for Valuation of Oil Properties*

By W. Irwin Moyer, Pittsburgh, Pa.

TWO methods for the rapid valuation of oil properties are in common use. The one best known and most widely used is the "per barrel" value, based on the present daily production of the well, without regard to its past performance or the history of the sand or pool from which it produces. The second method is the "time to pay out," or the length of time required for a well to place itself upon the credit side of the ledger, from which time the returns from its production (less the operating expenses) will be clear profit.

The time basis for valuation is also commonly used in the appraisal of an undeveloped lease. In most oil fields, it is not thought good business to invest in production that will not pay out in at least 4 to 5 years. Nearly all buyers (except in certain regions of very persistent production like the deep-sand territory of the Appalachian field) expect wells to pay out in considerably less time than this.

Like the barrel per day price, the time necessary for a well to pay out has been determined for each field, so that one frequently hears a field or district referred to as having a certain time to pay out. This is considered the norm for that field or district and the buyer and seller base their value, to greater or less extent, on their belief in the accuracy of this time.

The writer long ago became convinced of the inaccuracy of the barrel per day method, except when greatly modified for local conditions, such as the age of the wells, their economic limit, operating conditions in the field, the future price of oil, and the persistence of the sand as a producer. When so modified, this method becomes more of an analytic or predicted probable yield valuation. While the appraiser may not go through each step in a valuation based on future returnable revenue, his knowledge of the field and the local conditions surrounding his leases make it possible for him to estimate a fair sales value that, in many cases, will be a close approximation to the truth. This is quite different from the commonly understood barrel per day value, in that the conditions surrounding the sale of one lease or property at a fair market value may be entirely dissimilar from those of a nearby property and the per barrel price of the first property will form no criterion of value for the second.

The present paper is the result of an investigation made to determine the reliability of the time to pay out as a basis for valuation. The data used were decline curves of production from several widely scattered fields in the United States, the curves being compiled from the production records of a large number of wells in the same field.

Conclusions from the curves and tables are:

1. The time to pay out varies in all fields.

2. For different fields, the decline curve is an important source of variation.

3. For the same pool or field, of the factors that vary, the time to pay out, sale price for oil and size of well are most important. Of much less importance are drilling and operating costs.

4. When properly modified for these variations, by use of a series of time to pay out curves, based on the decline curve of the field, the method is of value either as a supplement to a detailed appraisal or as a check on a rapid approximate valuation.

5. The method may be used in connection with a barrel per day value with much less likelihood of error than though the barrel per day is based on the flush production of the well. After the well has paid out, its production will be settled to a degree permitting a more liberal use of the flat barrel price.

6. The curves show at a glance: The minimum size of paying wells; the minimum sales price for oil on which average wells can be drilled; the influence on profits of a fall or rise in price for oil.

*New York Meeting, February, 1922.

## Subsurface Conditions on Portion of Arches Fork Anticline*

By Kenneth Cottingham, Columbus, Ohio

THE area described is situated on the Arches Fork anticline in Roane and Calhoun Counties, West Virginia. When the area was first mapped, it was expected that well records would give a more intimate idea of conditions, both structural and lithologic, than could be expected from surface horizons, but such has not proved to be the case. The surface formations are chiefly members of the Monongahela series, although the northern hilltop outcrops are of the Dunkard. Neither series offers a key horizon sufficiently definite to be satisfactory, although the structure as determined from well records was later checked against two of the more persistent surface sandstones.

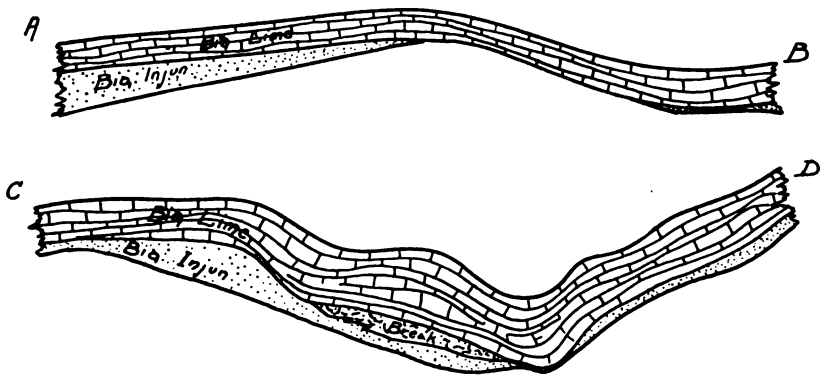
In mapping the subsurface structure, the top of the Big Lime (Greenbrier) was employed as the key horizon. The average depth to the top of the Big

*New York Meeting, February, 1922.

Digitized by Google

Lime varies from 1600 to 2000 ft., while the average thickness as indicated by well records is 113 ft. The oil-producing formation is the Big Injun, lying just below the Big Lime. In two instances, well records show the Lime and Injun separated by a few feet of "break." The Big Injun is recorded as having a variable thickness; seven logs report it as missing, and one gives it the maximum thickness of 105 ft. while the entire average for thickness is 19 ft.

The seven wells located near the anticlinal axis report the Big Injun as absent. They generally tend to show a thickening of the Injun on the flanks of the anticline, increasing with distance from the axis. Manifestly, this anomaly has no stratigraphic basis, as the actual thickness of the Big Injun and the overlying Big Lime was determined by original deposition which no amount of subsequent folding could appreciably alter. A skeleton map of structure and a cross-section showing the thickness of the Big Injun are given.



Cross-sections of Big Lime and Big Injun.

The recorded thickness of the Big Injun seems to have been based on the degree of show as an oil sand rather than on the actual amount of sand present. Recorded thicknesses of Injun in excess of 40 ft. undoubtedly include some Big Lime, and when the Injun is reported absent, it is probable that it was considered as part of the Big Lime.

It may be assumed that the Big Injun is more regular in thickness than the logs indicate, also that the actual thickness of the Big Injun bears no such direct relation to structure. Rather than defining the true thickness of the sand, cross-sections may indicate the attitude and capacity of a former reservoir from which the oil has retreated with a subsidence of the water level. The sand map shows that the apparent thickening of the sand, west of the no-sand area, balances the amount of dip on that side of the structure. Plotted in cross-section, it shows the base of the Injun dipping conformably with the top of the Big Lime, while the top of the Injun remains nearly level. This upper level undoubtedly lies in the basal portion of the Big Lime.

The no-sand area is slightly east of the anticlinal axis. Likewise, the oil sand is asymmetrical with respect to the structure, being thicker at a given distance on the western flank of the fold and lying structurally lower on the eastern flank. This again suggests an advance of water from the northwest, away from the axis of the Appalachian geosyncline. The minor thickening of the sand southwest of the no-sand area bears out the suggestion. The thickening of 20 ft. south of the same area is in part a break between the Big Lime and the Big Injun.

All the wells drilled along the axis of the anticline are reported to have yielded gas in some amount. None of the wells in the basin was commercially profitable and all were threatened by the water immediately after completion.

The evidence indicates an original advance of water from the northwest and a subsequent retreat in that direction. The leveling of the oil sand on the western flank of the anticline, the position of the no-sand area and the asymmetry of the sand with respect to structure, confirm this theory.

Whatever theoretical interpretation may be given to the facts, it is evident that an oil sand is frequently unreliable as a key horizon. In the present case, the sand indicates the extent and attitude of a former oil accumulation without giving an accurate conception of the structure.

## Investigation of Fatigue of Metals

A REPORT of the investigation of the fatigue of metals conducted by the Engineering Experiment Station of the University of Illinois in coöperation with the National Research Council, Engineering Foundation, and the General Electric Co., by H. F. Moore and J. B. Kommers, has been published by the University of Illinois, as Bulletin 124.

The introduction to the bulletin gives an outline of the inception of the investigation and of the method of work. During the war, the strength of airplane parts under repeated stress was of great importance. A short series of experiments on cold-dawn steel was made in the laboratories of the University of Illinois at the request of the National Research Council, which led to the investigation reported in Bulletin 124.

The national Research Council furnished an Advisory Committee to formulate general policies for the investigation; the Engineering Experiment Station provided a laboratory, the time of one member of its staff, and the use of much apparatus; Engineering Foundation first financed it, from the fund given by Ambrose Swasey; and, later on, the General Electric Co. contributed a sum of money that made possible the enlargement of the test party and the purchase of more equipment.

# Institute Affairs

## The Common Purpose

AT THE beginning of the year, it is a custom of humanity to look forward and make resolutions in respect to the things that it is going to do during the coming year, and it would be well if the Institute, in common with mortals, should do this. It can do so, for it is just as human as are those who compose it. The Institute is its members; and as they plan, so does the Institute plan and function. It is merely a group of men with a common purpose; and what those men resolve to do, they can do. The common purpose has been well defined in the Constitution of the Institute, but the paths leading to the desired ends are several and as time passes more and more of them appear to open.

Whether the mining engineers should all follow one path or take up diverse ways leading toward those ends that we feel are most desirable is an open question. We cannot all see eye to eye, but we can nearly all see work that should be done. One member is studying flotation, he desires to make his results public and have them criticized; another is working on a new group of alloys with peculiar physical properties; another is troubled with legal matters, he knows that he is not receiving justice, why should the Institute not help to have the law changed? Strikes in his coal mines are the bane of another's existence. Unjust taxation and confiscation of his Mexican property are the troubles of another, and he wants to know why the Institute does not call the attention of Washington to Mexican mining conditions; and so it goes. Some of the work that we would do or would have done falls within proper but narrow boundaries, while some goes far afield, and yet the man who sees its necessity thinks only of the fact that this is something that should be done and that mining men should see that it is done.

Whether it is the Institute's business to concern itself in many things that are of interest to mining men may be questioned, but it cannot be questioned that every man should plan to do the work that he thinks needs doing, using the Institute so far as he may In many cases it can help him and it will hinder him only when he is decided y on the wrong track.

F. F. SHARPLESS.

## From the Columbia Local Section

THE following is quoted from a postal which has just reached the Secretary's desk:

**While you are asking yourself, perhaps, "What is the A. I. M. E. or the local section doing for me," stop long enough to inquire what you are doing for the Institute or the section. The local section is the opportunity for individual direction and impulse; it demands your support and invites initiative. It should be the forum of the best things of local interest and of greatest value to fellow members. Are the name and address on the obverse side correct?**

This contains so much in such compact form that it is well worth reproduction for the benefit of those who are members or who should be members of other sections. The question has come to many, especially to the younger members and a better answer could not be written.

F. F. SHARPLESS.

## Summary of Minutes of November Meeting of Board of Directors

AT THE meeting of the Directors of the A. I. M. E. on Nov. 16, 1921, there were present 11 Directors, 17 guests, the Secretary and the Assistant Secretary of the Institute.

A resolution was passed authorizing the Secretary to issue a letter asking all members to indicate those subjects relating to mining in which they are particularly interested, and the subjects in which they specialize. A file containing this information will be of great value to the officers and members of the Institute.

The matter of revision of the U. S. Mining Law was referred to the sub-committee on Mining Law for consideration and action.

Twenty-two Members, 15 Associates and 9 Junior Associates were elected, and two former members were reinstated.

The following resolutions were unanimously adopted:

RESOLVED, That the Committee on Membership be instructed, and it hereby is instructed to require that a member who has been dropped for the non-payment of dues must pay all arrears of dues and other indebtedness, with which he was charged on the books of the Institute at the time he was dropped, before his application for re-election may be considered by the Committee. And be it further

RESOLVED, That a candidate for reinstatement, whether he be one that has resigned in good standing or one who was dropped and subsequently settled his indebtedness, may be required to submit a record covering the period of his non-membership, together with endorsements, just as in the case of a new candidate. On approval of the committee, the candidate may renew his membership by the payment of current dues and without the payment of a new initiation fee.

Digitized by Google

The name of William Kelly was substituted for that of John E. Hodge on the report of the Nominating Committee.

The Secretary was authorized to extend an invitation to the Mining and Metallurgical Society of America to hold a joint session with the Institute in February, if a satisfactory joint program is developed.

The following members of the Institute were elected to serve on joint activities: J. Vipond Davies, Board of United Engineering Society; John H. Janeway, member of Library Board; Herbert M. Boylston, member of Engineering Foundation; Herbert Hoover, member of John Fritz Medal Board of Award; George C. Stone, member of American Engineering Standards Committee.

By far the greater part of the meeting was devoted to a discussion of the budget for the year 1922. It is expected that the income of the Institute will be considerably less for the year 1922 than for the year 1921; hence some of the items of the budget for next year must be materially reduced, and the discussion was in respect to the items which should be reduced. It is hoped that the Finance Committee will have in hand sufficient data by the time the Board meets in January so that the budget may be submitted in its final form.

After authorizing the bills for the 1922 dues, the meeting adjourned.

## Transactions of the Electrical Engineers

PRESSURE on the finances and budget of the American Society of Electrical Engineers has led that society to take an unprecedented step in regard to the publication of their technical papers and the TRANSACTIONS.

This is a subject of vital importance to all societies, particularly at this time, when all are suffering more or less financial pressure. It has been thought wise to acquaint the members of our Institute with the steps taken by the electrical engineers, not with any intimation that a similar course may be followed by our Institute, but so that in their various considerations of our own problem they may be advised as to what other societies are doing in this respect.

### A. I. E. E. TRANSACTIONS

An important change in the policy to be followed in the distribution of the annual TRANSACTIONS of the Institute has been adopted, as explained in a notice issued to all members of the Institute under date of Nov. 12.

The volume covering the year 1920, publication of which has necessarily been delayed for financial reasons, is now completed and will be forwarded to all members entitled to receive a copy, during the month of December, 1921.

The new policy takes effect with the volume covering the year 1921 in accordance with the following resolution which was considered and approved by the Board of Directors at a meeting in October, 1920:

VOTED, that commencing with the volume of Institute TRANSACTIONS covering the year 1921, the practice of furnishing acopy of the TRANSACTIONS to each member of the Institute be discontinued, and that copies be furnished to all members who subscribe in advance at a price to be determined later, possibly $5 per year; the edition to be determined by the advance subscriptions received, with a reasonable allowance for stock to meet future demands.

The immediate occasion of the above action was the condition of the Institute's finances, caused by continuing all the activities of the Institute, at prevailing increased costs, without increasing the annual dues. The action was adopted after learning, through the Development Committee and through conference with the representatives of the various Sections at recent annual conventions, the attitude of the membership regarding the publications of the Institute.

The greatly increased cost of publishing the JOURNAL and TRANSACTIONS, together with the increased amount of suitable material available for publication, has rendered it necessary that the policy outlined above be now put into effect, and the following plan has been decided upon by the Board of Directors in connection with the 1921 and 1922 TRANSACTIONS

1921 TRANSACTIONS. This volume of the TRANSACTIONS is about to go to press, and the edition will be determined by the number of subscriptions received by Jan. 1, 1922, in response to the circular mailed to the membership Nov. 12. The price of the TRANSACTIONS will be $3 to the membership only. (The regular price to non-members will still apply.)

1922 TRANSACTIONS.—Commencing with this volume it has been decided to print each month in conjunction with the printing of the JOURNAL additional pages to be reserved and bound at the end of the year to form the volume of the TRANSACTIONS for those members who desire a file of papers and discussions in this form. The practice of printing discussions in the JOURNAL will be reestablished. The material to be contained in the TRANSACTIONS will be selected exactly as heretofore, the only difference in the volume being in the size of the pages, as pages from the JOURNAL will become identical with pages in the TRANSACTIONS, with the exception of a required change in folio numbers.

The edition of the TRANSACTIONS for 1922 will be based upon the number of members who make application therefor by Jan. 1, 1922, at the nominal price of $2 per year to the membership only.

The adoption of the above policy, resulting in the saving of a large portion of the expense caused by duplication of printing, will permit of the publication of additional desirable material, particularly relating to the activities of the Sections, and the further development of the JOURNAL in accordance with the policy decided upon in the fall of 1919, in response to the expressed wishes of the membership.

Each member who desires a bound copy of either the 1921 or 1922 TRANSACTIONS or both, is urged to make prompt application therefor, as only a limited number of surplus copies will be printed.

## Members, Please Note

REDUCED return fare in connection with the annual meeting may be obtained under the conditions noted on page 40. Read these conditions for the sake of the far-away members, if not for your own benefit. The amount of money involved will be small for those who live near New York, but unless they ask for the reduction members from distant points may be deprived of it.

# February Meeting Plans

IN THE December issue of MINING AND METALLURGY, attention was drawn to the February meeting of the Institute. The plans of the Committee on Arrangements have progressed considerably since that date, so that further announcements may now be made.

The Mining Methods Committee has definitely arranged for at least three sessions. One of these will be devoted to a discussion of various methods used in sampling large low-grade ore deposits; a second will have for its leading subject underground transportation and mining practice as developed by the Anaconda Copper Mining Co., and the third will be devoted to the coal industry, particularly in reference to the percentage of economic recovery under various conditions.

The Mining Methods Committee will also hold a committee meeting, which will be open to all members, for the purpose of a discussion in reference to the symposium on mining methods which it proposes to hold at an early meeting.

The Petroleum and Gas Committee is planning a two-day symposium. A tentative program was printed in the November number of MINING AND METALLURGY, and this, with a few changes, still indicates the plans of the committee. E. L. DeGolyer, vice-chairman of the committee, says:

> Mining engineers and geologists should make every effort to attend the February meeting and hear the symposiums on foreign oil possibilities which have been arranged by the Petroleum and Gas Committee of the Institute. No such comprehensive consideration of this subject as that planned has previously been attempted.
>
> This matter is extremely important to all persons who are users of petroleum or its products, and in our present civilization this classification includes every individual, but it is particularly important to the engineer who directs the production and use of power on a large scale.
>
> The United States produces currently about two-thirds of the world's oil but consumes more than it produces. We must look to outside areas for part at least of our petroleum requirements and the future market, because even American oil will be influenced largely by the ease and freedom with which this outside supply may be secured.
>
> It is important to you to know something of foreign prospects and conditions under which they may be developed.

As noted below, the Excursion Committee is providing for excursions to nearby petroleum refineries and plants where a variety of petroleum products are being manufactured.

The Iron and Steel Committee has planned several sessions. The paper by W. P. Barba and H. M. Howe, the Report of the Ingot Committee of the National Research Council on Acid Open-hearth Process as Practiced in America in the Manufacture of Gun Steels and Fine Steels Generally, will be presented at one session. This is one of the most informative papers on the open-hearth that has appeared in any literature for many years, and in connection with the paper by W. J. Priestley, on Effect of Sulfur and Oxides in Ordnance Steel, will be a fruitful source of discussion. The paper by W. R. Webster, Application in Rolling of Effects of Carbon, Phosphorus and Manganese on Mechanical Properties of Steel, will be a feature of one session. The subject has been of so much interest at Institute meetings in former years, and new researches have advanced it so greatly, that considerable discussion is expected.

In addition to the above, there will be papers on Effect of Time in Reheating Quenched Medium Carbon Steel Below the Critical Range, by C. R. Hayward, D. M. MacNeil and R. L. Presbrey, on Malleableizing White Cast Iron, by Arthur Phillips and E. S. Davenport, on Effect of Quality of Steel on Case Carburizing Results, by H. W. McQuaid and E. W. Ehn.

The Iron and Steel Committee will also hold a memorial meeting for J. W. Richards, chairman of the committee for many years.

Iron and steel men will be interested to know that the first Hunt medal will be given to Captain Hunt at the annual banquet, it having been already officially presented to him with appropriate ceremonies, and that Captain Hunt's portrait, by Emil Fuchs, will be presented to the Institute by his friends in the membership.

The Mining Committee of the National Safety Council will hold two sessions in connection with the Institute meeting, one of which will be devoted to hoisting, hoisting ropes and equipment; the other, to mine ventilation.

The Institute of Metals Division expects to hold two sessions. During one of the sessions, papers procured by the Division will be presented, and during the other certain work of the Bureau of Standards will be discussed. It is hoped, also, that during the meeting this group will be able to present the first of a series of annual lectures; the subject and the lecturer will be announced later.

It is hoped that sessions may also be arranged for discussion of non-metallic minerals.

There will be a convention of representatives from all the local sections, and opportunity will be offered for a meeting of all of the committees some time during the week.

The Excursion Committee plans visits to industrial plants near New York, dividing the excursion into three divisions—steel, copper and oil. The plans are for the steel group to visit the Crucible Steel Co. and the Pardee Steel and Tile Works, for the oil group to go to the Standard Oil plant at Bayway and the Chese-

Digitized by Google

brough Mfg. Co. or the Barber Asphalt Co.; and the copper group to visit the U. S. Metals Refining Co. at Chrome and possibly the Raritan Copper Works. Though all members with their ladies and guests can be accommodated in one or another of these divisions, a limited number only can be taken in any one division. It is requested, therefore, that members write as soon as possible to the chairman of the Excursion Committee, stating which division they wish to attend and how many ladies and guests they anticipate will accompany them. Address: Mr. R. W. Deacon, c/o U. S. Metals Refining Co., Chrome, N. J.

The Hotel Committee has reserved a limited number of rooms at five hotels as follows:

| | Single Rooms | | Double Rooms | |
|---|---|---|---|---|
| | With Bath | Without Bath | With Bath | Without Bath |
| Belmont..... | $6 up | $3.50 | $9 | $6 |
| Commodore..... | 4.50 up | | 6.50 up | |
| McAlpin..... | 4.50 up | | 8.00 up | |
| Pennsylvania..... | 4.50 up | | 6.50 up | |
| Waldorf..... | 6.00 up | | 9.00 up | |

Only a few rooms are available at the minimum rates but the committee will do the best possible to secure accommodations at prices desired. Members wishing accommodations at other hotels will be served, if possible. All applications should be made to Mr. Wilber Judson, c/o M. P. Guilfoil, 14 Wall St., New York, at as early a date as possible. No promise can be made for late reservations, though the committee will gladly do the best it can for members unable to make an early decision to attend. Washington's Birthday occurs in Institute week this year, therefore the hotels will be crowded.

On Monday evening, Feb. 20, a smoker will be held at the Institute building.

No program will be fixed for the evening of the 21st but arrangements have been made to secure theatre tickets in blocks for those who wish to attend in small parties of their own.

A number of the committees will also hold their meetings at dinners on the evening of the 21st; arrangements have been made for dinners of the Petroleum and Gas Committee, the Milling Methods Committee, and the Institute of Metals Division, and others are under consideration.

The annual banquet of the Institute will be held at the Pennsylvania Hotel on the evening of the 22nd. Announcements of this dinner and reservation cards will be sent to members in January.

## Reduction in Railroad Fares

The Institute has made arrangements whereby reduced rates will be granted, to members and dependent members of their families attending the meeting, for *return* railroad fares on most railroads in the United States, except from the states of Washington, Oregon, Nevada and California (these may be arranged for before the time of the meeting), on the following conditions. Keep in mind the fact that although the reduced fare may not be of importance to you, it may mean a great deal to the more distant member, and that it will not be granted to any one unless at least 350 certificates are validated. Members living near New York are urged to obtain certificates, so that those coming from a greater distance may secure the benefit of the reduced rate.

### *How to Obtain the Reduced Fare*

1. Tickets at the regular one-way adult tariff fares for the journey to New York must be purchased on certain specified dates. Some railroads will sell these tickets from Feb. 16 to 21; others will sell them from Feb. 16 to 22. Be sure that when purchasing your going ticket you request a "certificate," not a "receipt."

2. Present yourself at the railroad station for ticket and certificate at least 30 minutes before departure of train on which you will begin your journey.

3. *Certificates are not kept at all stations.* Inquire at your home station; the agent will inform you at what station they can be obtained. You can purchase a local ticket to the station which has certificates in stock and there purchase a through ticket and obtain a certificate.

4. Immediately on your arrival at Institute headquarters, present your certificate to the endorsing officer, John T. Breunich, as the reduced fare for the return journey will not apply unless you are properly identified as provided for by the certificate.

5. The special agent of the railroads will be in attendance on Feb. 22, to validate certificates. If you leave for home prior to his arrival, or if you arrive at the meeting after he has left, you cannot have your certificate validated and therefore you will not obtain the benefit of the reduction on the home journey.

6. The reduction on the return journey is not guaranteed, but is *contingent on an attendance of not less than 350 members and dependent members of their families*, holding regularly issued certificates obtained from ticket agents at starting points, showing payment of regular one-way adult tariff fares of not less that 67 cents on going journey.

7. If the conditions are met, you will be entitled, up to and including Feb. 27, 1922, to a return ticket *via the same route* over which you made the going journey at one-half of the regular one-way adult tariff fare from the place of meeting to the point at which your certificate was issued.

8. Return ticket issued at the reduced fare will not be good on any limited train on which such reduced fare transportation is not honored.

The Committee on Arrangements for the annual meeting is as follows:

Chairman, William Young Westervelt
Vice-chairman, Robert Linton
Secretary, E. L. Gruver

# New Amendments to Institute By-Laws

At the meeting of the Directors of the A.I.M.E. on Dec. 16, amendments which had been before the Board for three months were adopted. The former and the amended sections are as follows. Words from the original By-Laws omitted from the amendments are printed in italics and additions in the new By-Laws are printed in bold face type.

ORIGINAL BY-LAWS

BY-LAW I. P. 3

BY-LAW III. P. 1

The Secretary shall keep a record of the proceedings of all meetings of the Institute. He shall be custodian of the corporate seal, of the minute books and of all legal documents belonging to the Institute. He shall have charge on behalf of the Institute, of all correspondence *except such as pertains directly to the office of the Treasurer.*

P. 3

The Secretary shall be custodian of all technical or scientific papers submitted to the Institute for its consideration, shall have general charge and supervision of the editing and proofreading of all material published by the Institute and of the distribution thereof, *and be ex-officio Chairman of the Committee on Publications.*

P. 5

The Secretary may, with the approval of the Board of Directors, employ such persons as are necessary to constitute a clerical *and office* force, at such salaries as shall be approved by the Board of Directors or its Executive Committee. He shall be the immediate *superior* of all such employees.

P. 6

BY-LAW IV. Addition

BY-LAW V. P. 1

The Treasurer shall *collect* and, under the direction of the Board of Directors, shall disburse all funds of the Institute. He shall keep regular accounts in books belonging to the Institute, which shall be open to any member of the Board of Directors. He shall report in writing at each annual meeting of the Institute, and at every regular meeting of the Board of Directors the balance of money on hand, and any existing appropriations which may affect the same.

P. 5

BY-LAWS AS AMENDED

BY-LAW I. P. 3

**The president shall do and perform such other duties as may from time to time be assigned to him by resolution of the Board of Directors of the Institute.**

BY-LAW III. P. 1

The Secretary shall keep a record of the proceedings of all the meetings of the Institute. He shall be custodian of the corporate seal, of the minute books, and of all legal documents belonging to the Institute. He shall have charge on behalf of the Institute of all correspondence.

P. 3

The Secretary shall be custodian of all technical or scientific papers submitted to the Institute for its consideration, and shall have general charge and supervision of the editing and proofreading of all material published by the Institute, and of the distribution thereof.

P. 5

The Secretary may, with the approval of the Board of Directors, employ such persons as are necessary to constitute a clerical force, **including employees of the Accounting Department,** at such salaries as shall be approved by the Board of Directors or its Executive Committee. He shall be the immediate **supervisor** of all such employees.

P. 6

**The Secretary shall do and perform such other duties as may from time to time be assigned to him by resolution of the Board of Directors, and the Directors shall have power, by resolution, to take from the Secretary and to delegate to any other officer any of the duties of the Secretary.**

BY-LAW IV. Addition

**The Assistant Secretary shall do and perform such other duties as may from time to time be assigned to him by resolution of the Board of Directors, and the Directors shall have power, by resolution, to take from him and to delegate to any other officer any of the duties of the Assistant Secretary.**

BY-LAW V. P. 1

The Treasurer shall **receive** and, under the direction of the Board of Directors, shall disburse all funds of the Institute. He shall keep regular accounts in books belonging to the Institute, which shall be open to any member of the Board of Directors. He shall report in writing at each annual meeting of the Institute, and at every regular meeting of the Board of Directors, the balance of money on hand, and any existing appropriations which may affect the same.

P. 5

**The Treasurer shall do and perform such other duties as may from time to time be assigned to him by resolution of the Board of Directors, and the Directors shall have power, by resolution, to take from him and to delegate to any other officer any of the duties of the Treasurer.**

Digitized by Google

BY-LAW VI. P. 1

The Board of Directors may appoint an Assistant Treasurer, to whom it may delegate the duties *of conducting, under the supervision of the Treasurer, correspondence incidental to the office of Treasurer, of collecting*, receiving and depositing in bank, to the credit of the Institute, all moneys, and of paying out of a special account, if entrusted to him, the smaller current expenses of the Institute, subject to the instructions of the Treasurer. He shall hold no other office.

P. 2

BY-LAW VII. P. 4

The Committee on publications shall consist of the Secretary of the Institute, *who shall be its Chairman*, and at least twelve members of the Institute, to assist in passing on all papers offered for publication. They shall be appointed annually by the Board of Directors.

BY-LAW X. P. 1 (a)

On receipt of a paper by the *Secretary* (Chairman), he shall send it to the member of this Committee who, in his judgment, is most competent and available to pass upon it as "Reader," accompanying the paper with his own opinion of its suitableness for publication, and any other pertinent information.

P. 3

In case the *Secretary* is unable to secure a decision as to the suitability or unsuitability of a paper for publication, as directed in Section 1 before the time of announcing the program of a meeting, he may at his own discretion place the paper upon the program of the meeting, or refuse it a place thereon.

P. 4

The Secretary, being Editor of the Publications of the Institute *as well as Chairman of the Committee on Papers and Publications*, and being charged with the duty of seeing that expenditures authorized for publications by the budget are not exceeded, shall have the right to veto the publication of any paper. This veto may be reviewed by the Directors upon application.

BY-LAW XXII. Sec. 1

*Amendments to these By-Laws may be made* by vote of a majority of the Directors, *provided the amendments have been proposed by a member of the Board at a previous meeting of the Board and copies of the same sent to all members of the* Board at least 20 days before the meeting at which they are to be voted on, *and an expression of opinion invited thereon. At a later meeting they may be amended in form, but not in substance.*

BY-LAW VI. P. 1

The Board of Directors may appoint an Assistant Treasurer, to whom it may delegate the duties of receiving and depositing in bank to the credit of the Institute, all moneys, and of paying, out of a special account, if entrusted to him, the smaller current expenses of the Institute, subject to the instructions of the Treasurer. He shall hold no other office.

P. 2

**The Assistant Treasurer shall do and perform such other duties as may from time to time be assigned to him by resolution of the Board of Directors, and the Directors shall have power, by resolution, to take from him and to delegate to any other officer any of the duties of the Assistant Treasurer.**

BY-LAW VII. P. 4

The Committee on Publications shall consist of the Secretary of the Institute, and at least twelve members of the Institute, to assist in passing on all papers offered for publication. They shall be appointed annually by the Board of Directors.

BY-LAW X. P. 1 (a)

On the receipt of a paper by the Chairman, he shall send it t the member of this Committee who, in his judgment, is most competent and available to pass upon it, as "Reader," accompanying the paper with his own opinion of its suitableness for publication, and any other pertinent information.

P. 3

In case the Chairman is unable to secure a decision as to the suitability or unsuitability of a paper for publication, as directed in Section 1, before the time of announcing the program of a meeting, he may at his own discretion place the paper upon the program of the meeting, or refuse it a place thereon.

P. 4

The Secretary, being Editor of the publications of the Institute and being charged with the duty of seeing that expenditures authorized for publications by the budget are not exceeded, shall have the right to veto the publication of any paper. This veto may be reviewed by the Directors upon application.

BY-LAW XXII. Sec. 1.

**The Board of Directors shall have power to make, amend, and repeal these By-Laws,** by a vote of a majority of all the Directors, **at any regular meeting of the Board, PROVIDED, that notice of intention to make, amend, or repeal the By-Laws in whole or in part, shall have been given at the next preceding meeting, and copies of such amendments shall have been sent to all the members of** the Board at least (20) days before the meeting **at** which they are to be voted on.

# Activities of Local Sections and Affiliations

## Colorado Section Meets with Students

A JOINT meeting of the Colorado Local Section and the affiliated student society of the Colorado School of Mines was held at the armory in Golden on Nov. 22, at 6:30 p. m. Chairman Parker presided and 175 members and guests were present. Some members of the local section were seated at each table, so that the older members might become acquainted with the newer ones.

The meeting was opened by the singing of the "Star Spangled Banner." Grace was said by the Rev. G. L. Lehman. An excellent dinner was served by the ladies of the Episcopal Church, and during the dinner a number of popular songs were sung under the leadership of Lewis B. Skinner. After dinner the School of Mines band, led by Professor Bellis, rendered a number of selections.

Chairman Parker briefly explained the organization of Colorado Engineering Council and its plans for a Municipal Stadium and Engineer's Building in Denver, and H. B. Barnes outlined the idea of the proposed Engineers' Building. By request of Engineering Council, the chairman was directed to appoint a committee of three to confer with similar committees of the other member organizations of Council regarding plans for the building.

Arthur Thacher, of St. Louis, gave a delightful address in which he outlined the work that lies before engineers in coöperating with other agencies of civilization in assisting the progress of humanity. Mr. Thacher spoke of the important work that can be done by the Institute, and emphasized the necessity for individual responsibility.

President Alderson, of the School of Mines, T. S. Harrison, president of the School of Mines Alumni Association, Theodore Marvin, chairman of the School of Mines student society, Max Ball and Judge Stimson, spoke briefly regarding the benefits derived from membership in the Institute.

The "Skyrocket Cheer" was used in connection with the introduction of the speakers. This, in a certain sense, corresponds to the English Herald's announcement of a speaker or toast, but is considerably more lively.

## Geology of Spokane Region Studied by Columbia Section

ABOUT forty members and guests attended the November meeting of Columbia Local Section. Ivan de Lashmutt presided. Thomas Large, of the department of science of Lewis and Clark High School, read a paper on the Geology of the Spokane Region. This was discussed by Thomas A. Bonser, F. A. Thomson, F. M. Handy, Russell Collins, J. H. Eby, and others, who, although they agreed as to the principal physiographic features and doubted the presence of petroleum in commercial quantities, did not agree on the subject of the historical geology of the area. The same topic will be discussed at another meeting.

## Tulsa Section Nominations

NOMINATIONS for officers of the Tulsa Section for the year 1922 are:

Chairman—H. B. Goodrich, Tulsa, Okla.
Vice-chairmen—J. A. Udden, Austin, Tex.
Wallace E. Pratt, Houston, Tex.
Sidney Powers, Tulsa, Okla.
Sec.-treas.—Robert H. Wood, Tulsa, Okla.
Executive Committee—Alf. G. Heggem, Tulsa, Okla.
W. R. Hamilton, Tulsa, Okla.
Alexander Deussen, Houston, Tex
Charles H. Taylor, Oklahoma City, Okla.

## Southern California Section Begins Year's Work with Vigor

THE first meeting of the Southern California Section, this year, was held on Oct. 13. The real "get-together," "get acquainted" meeting started at 5.15 p.m. at the offices of the Western Precipitation Co. in Los Angeles. There, as guests of Walter Schmidt, chairman pro-tem of the section, the members were received and entertained. Each member, on entering the offices, was branded and instructed to roam at will through the numerous offices, laboratories, shops and drafting rooms. His brand was an introduction to every other member, his duty was to get acquainted. The company had its laboratory in full operation, giving a practical demonstration of its process of anti-precipitation and oxidation. This was keenly appreciated and enjoyed by all members.

This preliminary meeting insured the success of the dinner and business meeting that followed at the California Country Club, where 95 members and guests sat down at table. Chairman Schmidt announced informally that there should be more "pep" injected into the meetings, that there was much latent talent for entertaining among its members and that the old college spirit should be revived and exercised. He

Digitized by Google

called for volunteers to entertain by story and song. The response was fairly generous and the applause showed genuine appreciation and enjoyment.

At the conclusion of the dinner, the business meeting was called to order by the chairman. Mr. Schmidt explained that he was occupying the chair because the elected chairman, Harvey Mudd, had been called to Europe.

By resolution, the section approved the proposed constitution of the Federated California Technical Societies and its administrative body, the California Technical Council, and instructed its officers to arrange to have the section join the federation.

Horace V. Winchell, who was welcomed both as a past president of the Institute and as a new member of the local section, made an address on the Relation of Mining to Business. The unanimous opinion, brought out in discussion, was that Mr. Winchell's paper contained a prophetic message to the general public as well as to mining engineers, and that it should be published in the daily press. It appeared in the *Los Angeles Times*, Oct. 16, 1921.

Mr. Rogers, vice-president of the Merchants National Bank and Mr. Pettingell, president of the Los Angeles Stock Exchange, guests of the evening, gave interesting short talks.

As an epilogue to this meeting, Ira Remsen presented an animated puppet show entitled "The rock hounds of Ventura or the petroliferous pups," starring our fellow member, Harry Johnson, assisted by a company of six.

The November meeting of this section was held on Nov. 18, at the Canterbury Inn, Los Angeles. During the dinner attended by 54 members, a number of questions of general interest to the Southern California Section were discussed and the executive committee was authorized to arrange for a weekly "round table" at the Hoffman Cafe at luncheon time on Wednesday.

An outdoor meeting and barbecue, possibly at Topango Canyon, was suggested and was referred to the entertainment committee.

Mr. Nevius reported on the status of the real estate license law. He said that this matter is of vital interest to every engineer in California and should be followed up; the chairman therefore re-appointed Mr. Nevius as a committee of one to keep in touch with this subject.

It was moved and seconded that a committee of three be appointed by the chairman to study and report on the Bureau of Mines bill that is now before Congress.

Doctor Wood of the Carnegie Institute gave an interesting talk on Earthquakes and Prominent Fault Zones of the Pacific Coast, which was followed by brief discussion led by Doctor Ralph Arnold and Harry Johnson. The second speaker, Mr. LaRue of the United States Geological Survey, spoke on the Colorado River Power and Irrigation Project and showed some fine slides.

## Seattle Engineers Club Open to Institute Members

THE Puget Sound Section invites all members of the Institute who are planning to visit Seattle to write or wire the Engineers Club of Seattle, 5th and Seneca Streets, for reservations, saying in the application that they are members of the A. I. M. E. The officers of the local section will see that these visitors are supplied with guest cards and that the full privileges of the club are extended to them. The new club house has 22 rooms for guests in addition to library, billiard room, dining room and other rooms for general use.

The Puget Sound Section of the A. I. M. E. holds its meetings at the Engineers Club, and the local sections of the other national engineering societies also meet there. It is hoped that, eventually, an Engineers' Building may be erected in Seattle, to be the headquarters of the engineering activities of the city.

ENGINEERS CLUB, SEATTLE, WASH.

The section held a meeting on Nov. 26, at which the subject of discussion was the bill on the revision of the mining law now before Congress.

A 60-lb. fruit cake was sent to Herbert Hoover at Thanksgiving. The emblem of the Institute was placed on the cake and the accompanying card read "From the Puget Sound Section, American Institute of Mining and Metallurgical Engineers."

---

## What Can be Done to Revive the Mining Industry

THE regular monthly meeting of the New York Section was held at the Machinery Club on Wednesday, Dec. 7. The subject of the meeting, which was preceded by the usual informal dinner, was "What Can be Done to Revive the Mining Industry." The speakers of the evening were C. F. Kelley, president of the Anaconda Copper Mining Co. and Thomas H. Watkins, president of the Pennsylvania Coal & Coke Corpn., whose speeches will be printed *in extenso* in this magazine. They were followed by an impromptu address by Dr. Richard Moldenke, who has recently returned from several months in Germany. He discussed the inter-relation of American business and its

Digitized by Google

recovery with the recovery of European conditions, which at present are very difficult.

The attendance at the meeting was about 125. Dr. R. M. Raymond presided.

The New York Section will hold its next meeting on Jan. 11, at the Machinery Club. The dinner will be at 6.30, and the program at 8 p. m. The subject before the meeting will be "Compulsory Licensing of Mining Engineers."

## Affiliated Student Societies

**Miner's Club,** University of Arizona, held its first meeting of the year early in November, and elected the following officers: president, Speed Bugbee; vice-president, Ernest Hansen; secretary, George Roseveare; treasurer, Jack Still.

**School of Mines Society,** Columbia University, has resumed activities. The officers are H. Potter, president; M. Tynan, vice-president; H. Wachsmann, secretary.

**John Markle Mining Society,** Lafayette College, held its second meeting of the year on Nov. 2. Dr. G. B. Shattuck, acting professor of geology in the absence of Professor Peck, gave a most interesting talk on his adventures in the Bahama Islands. He went there as head of a geological and geographical expedition sent out by Johns Hopkins University. Doctor Shattuck told of starting from Baltimore on a two-master, accompanied by a number of men who had never been to sea before. He explained the formation of the coral reefs and described the wonderful plant and animal life. He told several shark stories, described his experience with mosquitoes, and his contact with leprosy, concluding with a few suggestions for safeguarding health in the tropics.

At a special meeting held on Nov. 16, Dr. Henry Mace Payne, of New York, gave a very interesting lecture on present mining conditions in Mexico, which he illustrated by 50 slides made from photographs taken during his recent trip to the mining regions of southwestern Mexico.

**Mining and Metallurgical Society,** University of Utah, holds a regular meeting from 4 to 6 p.m. on the first Wednesday of each month, at which lectures, pictures and instruction on subjects of interest to the mining fraternity are given. The officers of the society are: C. P. Caulfield, president; Alfred Dunyon, vice-president; Stewart Udell, secretary-treasurer.

**Mining and Metallurgical Association,** Missouri School of Mines, held a meeting in November that was attended by every eligible student in the school. C. H. Fulton, director of the School of Mines, and H. A. Buehler, state geologist and director of the Missouri Bureau of Geology and Mines, addressed the meeting on the subject of the importance of the Institute to the engineer.

**Scientific Society,** Colorado School of Mines, held its first meeting this year on Oct. 5. Addresses were made by Richard A. Parker, Thomas B. Stearns, Robert J. Grant, Frank E. Shepard, F. C. Gilbert, George A. Stahl, L. B. Skinner, V. A. Alderson, I. A. Palmer.

The officers elected for the year are: Theodore Marvin, president; A. C. P. Wong, vice-president; H. Ray Lee, secretary. The executive committee is composed of G. W. Baekeland, R. B. Lowe, H. H. Pratley, A. L. Pierce, L. S. Woeber, J. R. Dorrance, C A. Farlow, J. C. Herron, V. L. Denunzio, H. C. Colony, B. H. Parker, J. Dewey and the officers already named.

A membership campaign conducted under the guidance of Prof. J. C. Roberts, together with the energy developed at the first meeting of the society, has resulted in 90 applications for junior associate membership in the Institute.

A joint meeting with the Colorado Local Section of the Institute is described on page 43.

## Woman's Auxiliary

THE regular monthly meeting of the General Council of the W. A. A. I. M. E. was held on Thursday, Dec. 1, nine members being present.

The president reported the receipt of a copy of the Constitution of the Association of the Women of the Mining Industry of Canada from Mrs. Miller. This organization is the direct outgrowth of the Toronto Section of the W. A. A. I. M. E. Mrs. J. B. Tyrrell, its president, has been a member of our organization since the beginning, and as director of our Toronto Section has been enthusiastic in working out her ideal of an organization that should reach all women in the mining world of Canada. We congratulate Mrs. Tyrrell on the success of her efforts and also upon a well drawn constitution.

Mrs. Dwight, our president, while in Washington in November, had the great pleasure of meeting the members of the Washington Section of the Auxiliary. The following is quoted from the Washington *Star* of Nov. 10, 1921.

One of the most delightful entertainments of last week was the tea given at the Cosmos Club by the Washington Section of the Woman's Auxiliary, American Institute of Mining and Metallurgical Engineers, in honor of Mrs. Arthur S. Dwight of New York, president of the national organization. The society is composed of wives of engineers and scientists and is one of the largest and most important organizations for women in the United States. It has for its primary object the establishment of a fund for the education of young mining engineers, and rendering other service to the profession.

Tea was served in the drawing room of the club. Mrs. H. Foster Bain, wife of the director of the Bureau of Mines, presented the guests. Mrs. H. T. Mulliken, wife of the special technical assistant to the Bureau, presided at the tea table, assisted by Mrs. A. S. Spencer.

Digitized by Google

Mrs. Jennings, 2d vice-president, read a most interesting report of her recent trip through the West. In Salt Lake City, she was present at a meeting of the Utah Section of the Auxiliary, at the house of the director, Mrs. R. C. Gemmell; 20 members were present. In this section, each member taxes herself a small amount monthly, which is collected by the treasurer at each meeting, and is used in the work of the section. During the summer, the members made various garments to be distributed to relieve a little of the distress among the unemployed at Bingham.

In San Francisco, on the ninth of November, the following ladies met Mrs. Jennings at luncheon: Mrs. Charles Butters, Mrs. W. J. Crook, Mrs. Charles Janin, Mrs. Edmund Jüssen, Mrs. C. D. Kaeding, Mrs. T. A. Rickard, Mrs. W. H. Shockley. The organization of a section in Northern California is about to be completed.

The monthly luncheon of the New York Section was held at the Wiley's on Wednesday, Nov. 30. There were 49 present. The treasurer reported about $140 as the net proceeds of the card party given for the benefit of the Educational Fund, at Miss Stone's.

Mrs. Dwight read a communication from Mrs Harry Mulliken, secretary of the Washington, D. C., Section, describing the Christmas work being done, in sending books and toys to the children in various mining camps. Mrs. Knox Taylor read an appeal from Payson, Ariz., for books and playthings for children.

Mrs. Brown asked that the work of the Service Committee at the Soldiers and Sailors Club be continued during January, and it was decided that this should be done.

The speaker of the day was Mrs. H. Otto Wittpen, who has been a probation officer in New Jersey for many years and is well qualified to speak on "Delinquent Girls," the subject of her talk. Questions from the members, and a general discussion, followed.

# Government Action of Interest to Engineers

## Extracts from Weekly Bulletin Issued by American Engineering Council

DECEMBER 8, 1921

**New Division in Department of Commerce** to consider simplified commercial practices. It will be a subdivision of the Bureau of Standards. William A. Durgin of the engineering staff of the Commonwealth Edison Co. of Chicago has been granted a leave of absence to assume the direction of the work of the division which will be devoted entirely to the elimination of waste as applied to commercial practices.

**Annual Report of Commissioner of Patents** for the fiscal year ending June 30, 1921 shows an increase of 34 per cent. in the number of applications and an increase of 85½ per cent. in trade-mark applications. There were at the end of the fiscal year 49,334 patents awaiting action out of a total number of applications of 84,248. It also showed that the office had lost 163 scientifically and legally trained examiners, some of whom have been replaced by inexperienced men.

DECEMBER 1, 1921

**Federal Power Commission** at its next meeting will consider the much controverted "high dam" project on the Mississippi at St. Paul and Minneapolis. While it is fairly evident that the Northern State Power Co. can make most complete use of this project, which has considerable secondary power, its efforts are being actively opposed by Senator Nelson who claims that the company is a monopoly.

**Coal Industry and the Government.**—An effort is being made to work out a standardized contract to be used by the Government in the purchase of coal. The work on behalf of the coal men is being directed by George Reed of the Peabody Coal Company, Chicago, and F. R. Wadleigh for the Government.

NOVEMBER 23, 1921

**New Power Plants.**—The Geological Survey recently issued a map of New York showing the location of power stations and electric transmission lines used by the public utility companies. The map of Pennsylvania is now ready for distribution and maps covering New Hampshire and Vermont are nearing completion. Other maps in the super-power zone are being prepared in collaboration with the power companies.

**Mineral Industry.**—Two new pictures are ready for distribution from the Pittsburgh office of the Bureau of Mines. The first covers "The Story of Heavy Excavating Machinery," showing types of steam, gasoline, electric shovels and other heavy excavating apparatus used in mining operations. The subject of the second picture is "Mexico and Its Oil." It shows the technical operations of petroleum production in the great oil fields of Mexico.

## Investigations by the Bureau of Mines*

**Determination of Oxides of Nitrogen** (Technical Paper 249). By A. C. Allison, W. L. Parker, and G. W. Jones.—Describes a new method for the determination of this noxious gas, sometimes formed after blasting in metal mines.

**Oil-camp Sanitation** (Technical Paper 261). By C. P. Bowie.—Recommends remedial measures for faulty sanitation in oil camps. In the average mushroom community, sanitary conditions are so imperfect as practically to invite the visitation of a costly fire or epidemic. Many oil men employ the contract system of drilling, which almost eliminates the tendency of companies to build camps or small towns over which they may exercise personal supervision as to housing and sanitation.

The responsibility for the betterment of such conditions plainly belongs to the state governments; broadly speaking, all the states have legislation adequate to cope with these exigencies. The neglect of those in authority to meet these responsibilities brings hardship and unnecessary misery to a class of migratory workers who may be especially susceptible to the influence of social unrest.

In the older oil fields, although sanitary conditions are seldom all that can be desired, they are much superior to conditions in the new oil fields of less populated districts.

**Recovery of Unburned Fuel from Boiler-furnace Refuse** (Serial No. 2281). By Thomas Fraser and H. F. Yancey.—About 24 per cent. of our total production of bituminous coal is used in industrial power plants. As regards fuel conservation, therefore, the recovery of unburned fuel from furnace refuse presents interesting possibilities.

# Increase of Membership Department

**Total membership as of Dec. 17, 1921, is 10,329**

APPLICATIONS FOR MEMBERSHIP.—The Institute desires to extend its privileges to every person to whom it can be of service. On the other hand, it is not desirable that persons should be admitted to membership in classes for which they are not qualified. Members of the Institute can be of great service if they will make a practice of glancing through the list of applicants and promptly notifying the Committee on Membership, or the Secretary of the Institute, of any person whom they think should not be classified in accordance with the list given.

The following persons have been proposed during the period Nov. 20 to Dec. 17, 1921, for election as members of the Institute. Their names are published for the information of Members and Associates, from whom the Committee on Membership earnestly invites confidential communications, favorable or unfavorable, concerning these candidates. A sufficient period (varying in the discretion of the Committee, according to the residence of the candidate) will be allowed for the reception of such communications, before any action upon these names by the Committee. After the lapse of this period, the Committee will recommend action by the Board of Directors, which has the power of final election.

## Candidates for Membership

### Members

**1—Francisco Alayza y Paz Soldan,** Miraflores, Lima, Peru, S. A.
Present position: Director of the School of Arts and Trades of Lima.
Proposers: Fernando C. Fuchs, José Balta, José J. Bravo.

**2—Oliver Henry Bell,** Ely, Minn.
Present position—1920 to date: Chief Engineer, Vermillion Mining Company.
Proposers: Kenneth Duncan, William A. Rose, John C. Metcalf.

**3—Louis Burgess,** Elizabeth, N. J.
Present position: Chemist in charge of a Division of Research for the Standard Oil Co. (N. J.).
Proposers: Maurice Barnett, Frank H. Ramsey, Donald M. Liddell.

**4—Frank Carney,** Wichita, Kansas.
Present position—1917 to date: Chief Geologist, National Refining Co., Cleveland, Ohio.
Proposers: R. S. Hazeltine, Herman J. Allen, Marvin Lee.

**5—Cecil Reginald Clark,** Trinidad, B. W. I.
Present position—1919 to date: General Manager for British Controlled Oil Fields, Ltd.
Proposers: George B. Reynolds, E. K. Soper, L. L. Foley.

**6—Wilbur Ray Cusac,** Detroit, Mich.
Present position—1917 to date: Assistant Metallurgical Engineer, Dodge Brothers.
Proposers: M. H. Schmid, C. T. Bragg, M. T. Lothrop.

**7—Gustav Egloff,** Chicago, Ill.
Present position: Technical Director, Universal Oil Products Co.
Proposers: W. A. Williams, Van H. Manning, C. B. Dutton.

**8—John T. Fetherston,** Cuylerville, N. Y.
Present position: Manager, Sterling Salt Co.
Proposers: R. V. Norris, Edward W. Brown, Charles H. Snow.

**9—Charles David Heaton,** Egnar, Colo.
Present position—1912 to date: Superintendent, American Rare Metals Co.
Proposers: C. Montague Butler, W. H. Staver, Charles L. Harrington.

**10—Wilmot Carlyle Jones,** Freeland, Pa.
Present position: Mining Engineer, Wentz Co., Hazelton, Pa.
Proposers: T. E. Snyder, E. P. Humphrey, B. C. Osler.

**11—Carl Edward Mills,** Jerome, Ariz.
Present position—1920 to date: Chief Mining Engineer, United Verde Copper Co.
Proposers: Louis E. Reber, Jr., W. V. De Camp, H. De Witt Smith.

*Reports in full may be obtained from the Director of Bureau of Mines, Washington, D. C. Give serial number.

Digitized by Google

**12—Frank Pardee,** Hazleton, Pa.
Present position: President, Anthracite Separator Co.; Vice-President, Hazleton National Bank.
Proposers: I. P. Pardee, J. B. Warriner, Edwin Ludlow.

**13—Gordon Cecil Priddey,** Smethwick, Birmingham, England.
Present position—1914 to date: Chief Assistant Chemist, Works Manager, Chemist and Metallurgist, Henry Wiggin & Co., Ltd.
Proposers: H. M. Ridge, Ernest R. Woakes, Henry F. Collins.

**14—George A. Roos,** Pottsville, Pa.
Present position—1917 to date: Division Engineer, Philadelphia & Reading Coal & Iron Co., St. Clair Division.
Proposers: D. C. Ashmead, W. A. Richards, F. E. Powers.

**15—James W. Schwab,** Gulf, Matagorda Co., Tex.
Present position—1920 to date: Chemist, Texas Gulf Sulphur Co.
Proposers: Charles Biesel, H. E. Treichler, Walter H. Aldridge.

**16—Frank J. Smith,** Stambaugh, Mich.
Present position—1912 to date: Superintendent, Brule Mining Co.
Proposers: E. Leslie Laing, Rudolph Ericson, E. W. Hopkins.

**17—Lucien W. Smith,** Littleton, Colo.
Present position—1910 to date: Superintendent, Mt. Champin Mining Co.
Proposers: Frank E. Shepard, Robert W. Gordon, Horace F. Lunt.

**18—Beveridge Stead,** Paterson, N. J.
Present position: Not Engaged.
Proposers: F. H. Hayes, E. F. McCrossin, C. M. Staples.

**19—Emilio Alves Teixeira,** Passos, Minas, Brazil, S. A.
Present position: Topographic Surveyor in Passos County.
Proposers: H. H. Stoek, E. A. Holbrook, W. H. Staver.

**20—John Thomas Watson,** Eckman, W. Va.
Present position—1920 to date: Chief Engineer, Pulaski Iron Company.
Proposers: Floyd E. Cunningham, John J. Lincoln, R. A. Nowlin.

**21—Kentaro Yoshizawa,** New York, N. Y.
Present position—1920 to date: Chief Mining Engineer, Mitsui Mining Co.
Proposers: Kagakushi, T. Dan, Charles E. Locke, Robert H. Richards.

### Associates

**22—Edmund Carter Berkeley,** Van, W. Va.
Present position—1920 to date: Superintendent, Y. & O. Co.
Proposers: H. B. Turner, Ernest M. Merrill, Carl Scholz.

**23—Edward John Paul Fisher,** Worcester, Mass.
Present position: Metallurgist, Atlas Die-Casting Co.
Proposers: George R. Ensminger, William Campbell, Roysel J. Cowan.

**24—Wallace W. Fowler,** La Fundicion, Peru, S. A.
Present position: Chemist, Cerro de Pasco Copper Corporation.
Proposers: C. L. Baker, S. Sellner, Redick R. Moore.

**25—Wentworth Harrington Osgood,** Pittsburgh, Pa.
Present position—1912 to date: On Active Duty, U. S. Navy.
Proposers: L. G. Huntley, Roswell H. Johnson, R. E. Somers.

**26—Jens Christian Petersen,** Cerro de Pasco, Peru, S. A.
Present position: Assistant Superintendent, Cerro de Pasco Brick Plants.
Proposers: L. S. Breckon, M. R. Cuthbertson, John K. Walsh.

**27—John Barclay Rhodes,** Philadelphia, Pa.
Present position: Executive Officer, U. S. S. Huron.
Proposers: C. E. Margerum, John E. Arthur, 3rd, Charles R. Fair.

**28—Mark Howard Secrist,** Baltimore, Md.
Present position—1919 to date: Graduate student in geology, Johns Hopkins University.
Proposers: Edward B. Mathews, Joseph T. Singewald, Jr., W. Armstrong Price.

### Junior Associates

**29—Everett Philip Andrews,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: C. R. Forbes, J. R. Guiteras, C. L. Dake.

**30—Paul Wesley Banks,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, Victor C. Alderson, Lester S. Grant.

**31—Morris K. Barrett,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, Victor C. Alderson, Lester S. Grant.

**32—William Earl Clark,** Columbus, Ohio.
Student, Ohio State University.
Proposers: H. E. Nold, William A. Mueller, William J. McCaughey.

**33—Tristram Coffin Colcord,** Morgantown, W. Va.
Student, West Virginia University.
Proposers: A. C. Callen, David B Roger, I. C. White.

**34—Arthur Presely Davidson,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, Victor C. Alderson, Lester S. Grant.

**35—Ray Jackson Farmer,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: I. A. Palmer, J. C. Roberts, Victor C. Alderson.

**36—Joseph Lee Fearing,** Cambridge, Mass.
Student, Harvard Engineering School.
Proposers: Alfred Wandke, George S. Raymer, L. C. Graton.

**37—James M. Fergotson,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: M. H. Thornberry, Charles Y. Clayton, C. R. Forbes.

**38—Jack E. Fyfe,** Socorro, N. M.
Student, New Mexico State School of Mines.
Proposers: T. W. Quayle, W. G. Ramlow, B. H. Kinney.

**39—Chester Merle Gardiner,** Berkeley, Cal.
Student, University of California.
Proposers: Frank H. Probert, Lester C. Uren, Ernest A. Hersam.

**40—Charles Allen Gibbons,** Morgantown, W. Va.
Student, West Virginia University.
Proposers: A. C. Callen, David B. Reger, I. C. White.

**41—Joseph John Haberthier,** Rolla, Mo.
Student, Missouri School of Mines and Metallurgy.
Proposers: C. R. Forbes, Joseph R. Guiteras, C. L. Dake.

**42—Walter Joseph Heiler,** Pittsburgh, Pa.
Student, Carnegie Institute of Technology.
Proposers: Fred. Crabtree, Charles R. Fettke, R. Z. Virgin.

**43—Lawrence Carl Keeley,** Madison, Wis.
Student, University of Wisconsin.
Proposers: Clifton S. Corbett, A. N. Winchell, W. J. Mead.

**44—Edward A. Kilinski,** New York, N. Y.
Graduate student, Columbia University.
Proposers: James F. Kemp, Charles P. Berkey, R. J. Colony.

**45—Edgar DeWitt Klinger,** State College, Pa.
Student, Pennsylvania State College.
Proposers: William R. Chedsey, C. A. Bonine, E. S. Moore.

**46—Ben McColloch Layton,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: C. R. Forbes, C. L. Dake, J. R. Guiteras.

**47—Howard Chapin Lewis,** Appleton, Wis.
Student, Lawrence College.
Proposers: Rufus M. Bagg, Richard S. McCaffery, Thomas W. Orbison.

**48—Earl Hollinger McAlpine,** Rolla, Mo.
Student, Missouri School of Mines and Metallurgy.
Proposers: C. R. Forbes, J. R. Guiteras, C. L. Dake.

**49—Fulton Young Magill,** Tacoma, Wash.
Student, University of Washington.
Proposers: Milnor Roberts, Joseph Daniels, C. R. Corey.

**50—John Fuller Malony,** Stanford University, Cal.
Student, Stanford University.
Proposers: W. F. Dietrich, Theodore J. Hoover, Bailey Willis.

**51—James Rea Maxwell, Jr.,** Cambridge, Mass.
Student, Massachusetts Institute of Technology.
Proposers: Carle R. Hayward, H. O. Hofman, W. Lindgren.

**52—Casper Alexander Michelson,** Salt Lake City, Utah.
Student, University of Utah.
Proposers: Robert H. Bradford, Frederick J. Pack, James T. Norton.

**53—Walter Scott Moore,** Morgantown, W. Va.
Student, West Virginia University.
Proposers: A. C. Callen, David B. Reger, I. C. White.

**54—Charles Clifford Mosena,** Rolla. Mo.
Student, Missouri School of Mines.
Proposers: Charles Y. Clayton, C. L. Dake, C. R. Forbes.

**55—Albert J. Phillips,** New Haven, Conn.
Student, Sheffield Scientific School.
Proposers: C. H Mathewson, R. K. Warner, Arthur Phillips.

Digitized by Google

**56—Jack Cooley Pratt**, Houghton, Mich.
Student, Michigan College of Mines.
Proposers: J. B. Cunningham, Richard V. Ageton, Guy E. Ingersoll.

**57—Pierre Rondon**, Socorro, N. M.
Student, New Mexico State School of Mines.
Proposers: T. W. Quayle, W. G. Ramlow, B. H. Kinney.

**58—James W. Stewart**, Morgantown, W. Va.
Student, West Virginia University.
Proposers: A. C. Callen, David B. Reger, I. C. White.

**59—Milo Whitney Summers**, Bethlehem, Pa.
Student, Lehigh University.
Proposers: Howard Eckfeldt, Benjamin L. Miller, G. A. Roush.

**60—Evan Gwynne Thompson**, Madison, Wis.
Student, University of Wisconsin.
Proposers: Clifton S. Corbett, W. J. Mead, A. N. Winchell.

**61—Frederick Francis Truebger**, Rolla, Mo.
Student, Missouri School of Mines.
Proposers: C. R. Forbes, J. R. Guiteras, C. L. Dake.

**62—Herman Frederick Valentine**, Rolla, Mo.
Student, Missouri School of Mines.
Proposers: Charles Y. Clayton, C. R. Forbes, Joseph R. Guiteras.

**63—Everett John Wendell**, Rolla, Mo.
Student, Missouri School of Mines.
Proposers: C. R. Forbes, J. R. Guiteras, C. L. Dake.

Change of Status—Associate to Member

**64—Roscoe Everett Shutt**, Mexico, D. F., Mexico.
Geologist, Standard Oil Co. of California.

**65—Henry Tackmann**, Rosiclare, Ill.
Present position: Engineer, Fairview Fluorspar & Lead Co.
Proposers: W. C. Bohn, Lincoln A. Stewart., E. C. Reeder.

Change of Status—Junior Associate to Member

**66—Ulysses Henry Berthier**, Monterrey, N. L., Mexico.
Present position—1920 to date: Refinery Superintendent, Monterrey Smelter, Cia. Minera de Penoles, S. A.

**67—Harold Lippert Rau**, Milwaukee, Wis.
Present position—1920 to date: Field Oil Geologist, Lower fields, Mexico, with Cia. Mexicana de Petroleo, "El Aguila" S. A., Tampico, Mexico.

Change of Status—Junior Associate to Associate

**68—Harvey Hardison**, Coalinga, Cal.
Present position: Geologist, Associated Oil Co.
Proposers: Frank H. Probert, Ernest A. Hersam, Lester C. Uren.

HARRISON W. CRAVER, Director

## Book Review

**Mine Accounting and Cost Principles.** By T. O. McGrath. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 257 pp., tables, 9×6 in., cloth, $4.

This book by the auditor for the Shattuck-Arizona copper Co. is quite different from any other of the many books on mine accounting. After a statement of general principles it begins with the original money that may be put up for the purchase of a mine, say in the East where most of such money is raised, and goes through the operation of issuing stock, opening stock ledgers, etc., and a set of administrative books for the eastern office.

It takes the reader through the payment for the property, through a set of books and accounts during the development period of the mine and performs all the bookkeeping and accounting operations required when the mine goes from a developing to a producing basis. It takes up all the complicated details of bookkeeping and accounting for the mine product as it goes to the mill or smelter, some metallurgical bookkeeping, and the still more complicated accounts required in the final sale of the product, the example given being copper. It disposes of the sales receipts to dividends, capital return, surplus, etc., and returns operating money to the mines.

This book has the following advantages:

1. It covers the entire business of a mining accounting system from start to finish.
2. It treats the matter in narrative, or lecture form, which gives a continuity to the subject that not only adds to its clarity but robs it of its normally inherent dryness.
3. It not only tells what to do, but by example and specific entries shows how it is done.
4. It deals with the very complex subjects of depletion and depreciation as required by the new Income Tax Laws and shows how the corresponding accounts should be handled.
5. It is a book for both the accountant and the bookkeeper.
6. It has many bookkeeper's helps which make for office efficiency as well as accounting efficiency.
7. It shows how to compile, distribute and report mine operating costs, which is a most difficult problem.

P. E. B.

## Book Notices

**Annals of American Academy of Political and Social Science.** May, 1920. Vol. 89, No. 178. 289 pp., 9 × 6 in., paper. $1.25.

Essays by well-known economists, business men and engineers, discussing economic significance of present day prices, price factors in typical commodities, wages, profits and excess profits taxes, production, coöperation, international finance and trade in their relation to prices, inflation and prices, and world's monetary problems.

**Bleaching.** By S. H. Higgins. Manchester, University Press; Lond. and N. Y., Longmans, Green & Co., 1921. 137 pp., 9 × 6 in., cloth, $3.75.

Important researches of recent years discussed as a basis for further research. Book is intended to be a supplement to other books dealing with this industry.

**Central Station Rates in Theory and Practice.** By H. E. Eisenmenger. Chicago, Frederick J. Drake & Co., 1921. 382 pp., illus., 7 × 5 in., fabrikoid.

Textbook for students of electric rates, for beginners as well as experts. Discusses cost of electric service, its price, systems of charging, rate analysis, accuracy of rates and regulation of public utilities. Appeared serially in *Electrical Review*.

**Centrifugal Pumps.** By J. W. Cameron. Lond., Scott, Greenwood & Son, 1921. 142 pp., illus., 9 × 6 in., cloth, $3.75. (Gift of D. Van Nostrand Co.)

Discusses theory of these pumps, hydraulic losses, hydraulic efficiency, bearings, effect of vane angle on efficiency, pump details, axial thrust balancing, calculation and design of pumps, and commercial types. For engineers and draftsmen.

**Chemical Disinfection and Sterilization.** By Samuel Rideal and E. K. Rideal. Lond., Edward Arnold & Co., 1921. 313 pp., 9 × 6 in., cloth, $7.50. (Gift of Longmans, Green and Co.)

Summarizes some of the more important applications of general methods for sterilization of food, air and water, for public and private disinfection, for extirpating non-bacterial parasites and for preserving wood. Describes chemicals employed in disinfection, and methods for their analysis and testing. Contains numerous bibliographies.

**Chemical Warfare.** By Amos A. Fries and Clarence J. West. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 445 pp., illus., 8 × 6 in., cloth, $3.50.

History of the Chemical Warfare Service of the Army during the World War; intended also as a textbook for the Army, the reserve officer and the chemist.

**Coal, Oil, Gas, Limestone, and Iron Ore Map.**—West Virginia Geological Survey, Box 848, Morgantown, West Va. Scale, 8 miles to the inch. Price, folded in strong envelope and delivered by mail, $1; 6 copies for $5.

Thoroughly revised, showing oil and gas pools, many anticlinal lines not heretofore shown, with booklet giving names and addresses of principal coal-mining operators in West Virginia up to July 1, 1921.

**Coke-oven and By-product Works Chemistry.** By Thos. Biddulph-Smith. Lond., Charles Griffin & Co., Ltd.; Phila., J. B. Lippincott Co., 1921. 180 pp., illus., plates, 9 × 6 in., cloth, $7.

Concise manual of methods of chemical analysis covering general work required for chemical control of by-product coking plants, for works managers and chemists. An appendix gives a general survey of substances obtainable by distilling coal tar.

**Condensed Catalogues of Mechanical Equipment.** American Society of Mechanical Engineers. Eleventh annual volume, Oct., 1921. 932 pp., illus., 9 × 6 in., cloth, $4.

Four thousand firms are listed, under 3000 classes; 495 have data about their products in the book. One thousand consulting engineers are classified under 400 lines of specialization.

Digitized by Google

**Combustibles Liquides et Leurs Applications.** Syndicat d'Applications Industrielles des Combustibles Liquides. Paris, Gauthier-Villars et Cie, 1921. 621 pp., illus., 6 × 4 in., cloth.

Gives regulations governing importation and use of liquid fuels, insurance laws, brief descriptions of chief oil-producing countries, principal fuel oils and lubricants and methods for testing them. Describes leading French types of internal combustion engines, furnaces and boilers and gives directions for storing and shipping oil. Contains conversion tables and coefficients.

**Diagnosing of Troubles in Electrical Machines.** By Miles Walker. Lond. and N. Y., Longmans, Green and Co., 1921. 450 pp., diagrs., 10 × 7 in., cloth, $10.50.

Discusses troubles due to defective insulation, over-heating, low efficiency, and those peculiar to alternating and direct-current generators and motors, synchronous converters, motor generators and induction motors. Especially concerned with troubles in the field, not with factory tests.

**Early Science in Oxford.** Part 1. Chemistry. By R. T. Gunther. Lond., Hazell, Watson and Viney, Ltd., 1920. 91 pp., illus., plates, 8 × 6 in., paper, $3.50. (Gift of Oxford University Press, American Branch.)

Traces the story from its beginning with Roger Bacon in 1214 down to the early nineteenth century.

**Electrons and Ether Waves.** Twenty-third Robert Boyle Lecture. By Sir William Bragg. Lond. and N. Y., Oxford University Press, 1921. 14 pp., 9 × 6 in., paper. $0.45.

Discusses connection between ether waves and electrons and relation between wave length of ether radiations and velocity of ejected electrons. Gives a non-mathematical account of present information.

**Elektrische Fördermaschinen.** By W. Philippi. Leipzig, S. Hirzel, 1921. 304 pp., illus., 9 × 6 in., paper.

Use of electric hoisting machinery in mining is covered from several viewpoints, mechanical, electrical and economic, with special stress upon the last aspect of the question.

**Éléments d'Analyse Mathématique.** By Paul Appell. 4th edition. Paris, Gauthier-Villars et Cie, 1921. 715 pp., 10 × 7 in., paper. 65 fr.

Textbook of elements of mathematical analysis for engineers and physicists. Particular attention is given to use of analysis in geometry, physics and mechanics. All theories are illustrated by application to particular cases.

**Employment Management, Wage Systems and Rate Setting.** First edition. N. Y., The Industrial Press, 1921. 103 pp., 9 × 6 in., paper. $1.

Concise description of systematic methods of employing and placing men, and of wage payment systems, based on articles that have appeared in *Machinery*.

**Die Förderung von Massengütern.** By George von Hanffstengel. Vol. 1. Berlin, Julius Springer, 1921. 306 pp., illus., 9 × 6 in., cloth. 234M.

Deals with belt, chain, bucket, screw, spiral, pneumatic and hydraulic conveyors. Covers modern practice very thoroughly. Has been thoroughly revised for third edition.

**Foundations of Chemical Theory.** By R. M. Caven. N. Y., D. Van Nostrand Co., 1921. 266 pp., diagrs., 9 × 6 in., cloth, $4.

An account of the meaning of modern chemistry without multitudinous facts, for the student and general reader.

**Graphical Methods.** By William C. Marshall. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 253 pp., charts, 9 × 6 in., cloth. $3.

Treatise on construction and use of graphical charts. Gives examples of application of charts to many purposes and contains an extensive bibliography of published charts.

**Handbook for Field Geologists.** By C. W. Hayes. Third edition, revised and rearranged by Sidney Paige. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 166 pp., illus., 7 × 5 in., fabrikoid. $2.50.

Pocket size manual giving summary of methods and instruments most useful in field work, with outlines and schedules covering investigations in the several fields of geology. Contains an appendix on mineralogy.

**Invention the Master-key to Progress.** By Bradley A. Fiske. N. Y., E. P. Dutton & Co., 1921. 356 pp., illus., 8 × 6 in., cloth. $4.

An interesting account of what inventors have accomplished through the ages, and a forecast of what may be done in the future, if the art of invention is properly fostered.

**Manual of Determinative Mineralogy.** By Charles H. Warren. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 163 pp., 7 × 5 in., fabrikoid. $2.

To supplement descriptive text and crystallography. Represents course given in Massachusetts Institute of Technology.

**Mechanical Handling of Goods.** By C. H. Woodfield. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Technical primers.) 116 pp., illus., 6 × 4 in., cloth, $0.85.

To enable the unitiated to understand methods and equipment employed and appreciate economic possibilities of dealing with goods by mechanical methods.

**Mining Physics and Chemistry.** By J. W. Whitaker. Lond., Edward Arnold & Co., 1921. 268 pp., diagrs., tables, 7 × 5 in., cloth. $3. (Gift of Longmans, Green & Co.)

Introductory textbook giving knowledge needed by underground miner or official, particularly in collieries. Ventilation, spontaneous ignition, explosions and explosives, waters, mine gases, etc. are treated in simple language.

**Oil-field Practice.** By Dorsey Hager. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 310 pp., illus., diagrs., 7 × 5 in., fabrikoid. $3.

Subjects treated are acquisition of lands, development drilling, development production methods, transportation, storage, fires, avoidable wastes and losses, refining methods, valuation and buying, etc. Appendix contains sample forms for records, useful tables and a glossary. The book presents American methods. To a certain extent it supplements the author's earlier work, "Practical Oil Geology."

**Physical Properties of Colloidal Solutions.** By E. F. Burton. Second edition. Lond. and N. Y., Longmans, Green and Co., 1921. (Monographs in physics.) 221 pp., illus., 9 × 6 in., cloth. $4.25.

Outline of study of colloidal solutions particularly their relation to development of physics. Extended description is given of development of the ultra-microscope and confirmation of the kinetic theory of matter by the Brownian movement.

**Profit Sharing by American Employers.** Report of Profit Sharing Department of National Civic Federation. N. Y., E. P. Dutton & Co., 1921. 416 pp., 8 × 5 in., cloth. $8.

The first edition, published in 1916, was based on analyses of more than 200 plans for profit-sharing in use in this country. This edition is practically a new book; much of the former material has been omitted and numerous additions have been made, bringing it up to 1919.

**Railway-signaling.** By Everett Edgar King. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 371 pp., illus., diagrs., 9 × 6 in., cloth, $4.

Common practice in railway signalling presented in text-book

Digitized by Google

form, for beginners. Book discusses signal indications, interlocking, block signaling, signal mechanisms and highway crossing signals.

**Special Libraries Directory.** Edited by Dorsey W. Hyde, Jr. Wash., Special Libraries Association, 1921. 123 pp., 9 × 6 in., paper. $2.

Comprehensive survey of specialized collections of literature upon various subjects in the United States. Over 1300 libraries belonging to universities, societies, business houses and other agencies are listed by subject and also geographically. Valuable to research students, in indicating sources of information.

**Steam Engine Valves and Valve Gears.** By E. L. Ahrons. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Technical primers.) 112 pp., illus., 6 × 4 in., cloth, $0.85.

Concise description of usual forms of steam engine valves and valve gears, and an explanation of their action.

# Employment Service Bureau

Notices for this column are not acknowledged by letter. Notices recieved before the 15th of the month will appear in the next issue.

Correspondence relating to replies to advertisements returned to the Employment Bureau will be held in the Bureau for one month.

Positions of the Bureau are on file in the offices of the member societies of the Federated American Engineering Societies and with secretaries of A. I. M. E. local sections.

## Engineers Available

**Petroleum Geologist.**—Graduate. Two years in Mexico in charge of field parties for oil company. Speaks Spanish fluently. Age 26. Single. Engaged in Eastern states but wishes to return to foreign work. New York or Pittsburgh interview. IM-1519.

**Mining Engineer.**—Technical graduate. Seven years practical experience. Speaks Spanish. Age 31. IM-1520.

**Metallurgical Engineer.**—Graduate. Successful research and operating experience in iron and steel and non-ferrous alloys. IM-1521.

**Engineer.**—Member A. S. C. E. & A. I. M. E. with office in New York city desires to act as engineering, purchasing, or sales representative whole or part time, fee or commission basis. IM-1522.

**Mining Engineer.**—Graduate 1916. Experienced mine foreman in Wisconsin, Kansas, Oklahoma zinc fields. Engineer for large copper company. Speaks some Spanish and French. Prefers foreign appointment. IM-1523.

**Mining Engineer.**—Technical graduate. Seventeen years management, development and examination of mines in United States, Mexico and South America. Prefer New York headquarters, but would live elsewhere. Willing to go on trips. Available in New York City. IM-1524.

**Manager or General Superintendent.**—Fifteen years developing mines and in construction of large plants. Would consider foreign engagement with large company. Age 38. IM-1525.

## Positions Open

**Transmission Line Superintendent.**—Must be conversant with practice in transmission lines, 100,000 volt, three phase, 50 cycle. Capable of taking entire charge of transmission system of approximately 400 miles of lines; familiar with construction and operating work, and capable of handling native help. Reply stating age, experience, training and salary desired. India. X-1292.

**Engineer** to take charge of electrolytic silver refinery. Apply by letter only. Must have experience in this work. Mass. X-1314.

**Engineer** acquainted with Zaragosa Columbia territory and able to make careful test and ore map of 28 mines, including placers of about 5000 acres and quarts mines. Small investment necessary. X-1432.

**Chemical Engineer.**—Must have actual experience in production of hydrogen peroxide in large quantities and be able to take full charge of operations, including analytical determinations, processing, plant equipment, purchase of materials, and shipments. New Jersey. X-1437.

**General Superintendent** for foundry, coreshop, machine shop and pattern department. Must be experienced in shop organizing, efficient operation, and familiar with methods of securing maximum production. Pennsylvania. X-1448.

**Metallurgical Engineer.**—Expert in electrolytic partition of gold and silver. Apply by letter. Only engineers with this experience will be considered. South America. X-1449.

**Salesman** experienced in electric-arc welding and welding repair work. Apply by letter, stating age, education and welding experience. X-1455.

**Foundry Executive.**—To take charge of medium size foundry manufacturing plumbing supplies, etc. Must be capable office manager, understand cost accounting, payroll work, and have sales experience. Kansas. X-1458.

**Draftsman for Structural Steel.**—Single man preferred. Position may not prove permanent, on account of unsettled condition of copper camps. Arizona. X-1472.

**Young Man** experienced in brass manufacturing as assistant superintendent in a foreign country. Give concise record of experience, qualifications and salary expected. X-1474.

**Salesmen.**—Two technical men who have had underground metal-mining experience. Between 25 and 35 years old. Headquarters Butte, Mont. and Phoenix, Aris. X-1475.

**Engineer** with practical converter experience in metallurgy of copper. Apply by letter, stating age, education and experience. X-1529.

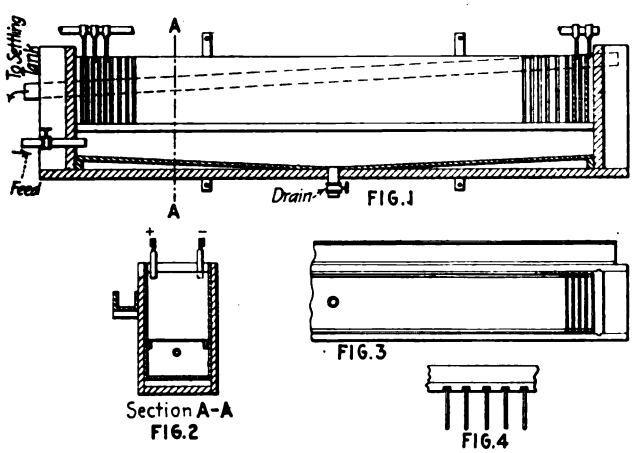
# Industrial News and Developments

Devoted to manufacturing and trade news of interest and value to the mining and metallurgical industry and invited from manufacturers and dealers. Scrutinized but not vouched for by the Institute.

## Stimulation of Free Settling by Electrolysis

RECENT efforts on the part of a number of coal operators in the anthracite fields of Pennsylvania to handle slush from their coal breakers at a profit, and at the same time stop stream pollution, makes timely a process patented by C. E. Holland. This process is intended to clarify any water containing finely divided solids in suspension by passing the water between electrodes through which in turn is passed direct electric current of low voltage. The material in suspension in the electrolyte



ELECTROLYTIC MACHINE USED IN HOLLAND PROCESS.

appears to act as a conductor and each particle becomes ionized. The result is a very rapid coagulation and settling of the material from suspension.

Slush water from the modern breaker contains from 5 to 15 per cent. solids by weight, all of which will pass a $\frac{3}{32}$ in. round-hole screen. It has been demonstrated that, by the use of Dorr thickeners, all plus 150-mesh material can be dewatered and recovered, but the minus 150-mesh material consisting of fine coal with various percentages of ash, on account of its low specific gravity and finely divided state, will remain in suspension indefinitely. By the Holland process, this material can be given a slight electrolytic treatment, which will cause it to settle rapidly so that a thickener will dewater it and will discharge an underflow containing not more than 40 per cent. moisture.

This treatment will mean an absolutely clear water that can be re-used for industrial purposes after being discharged to the rivers. When mine water containing several grains of sulfuric acid per gallon is used for washing coal, even the slight electrolytic treatment required to ionize the material in suspension will at the same time considerably decrease the acid content and a prolonged treatment will entirely eliminate the acid if soluble anodes are used.

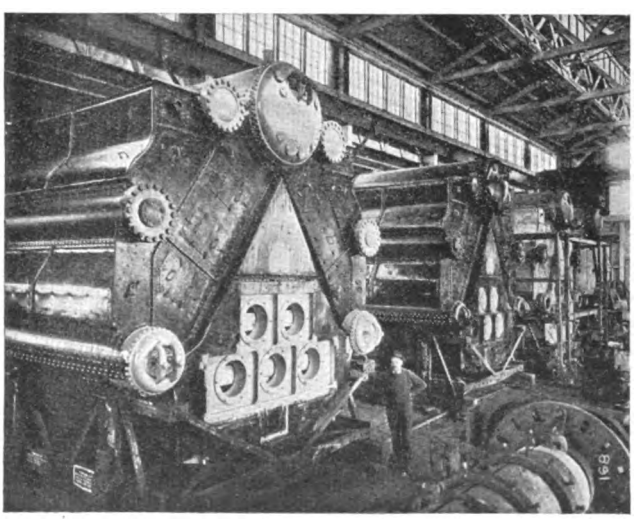
Filtering and drying experiments conducted by means of the Portland filter and Lowden dryer have demonstrated that the recovered material can be filtered and dried to give a bone-dry pulverized fuel, at a reasonable cost. Although this product will contain from 25 to 50 per cent. ash content this can be greatly lowered by flotation before the thickened pulp is sent to the filters.

Mr. Holland's experimental apparatus was installed and operated at the breaker of the Pennsylvania Coal Co. at Old Forge Pa., under the supervision of the Department of Health of the State of Pennsylvania, and the engineers of the Department report that all suspended matter was precipitated and that there was a current consumption of 0.8 kw. per thousand gallons of water treated or 9.5 kw. per ton of solids recovered.

A sketch of Mr. Holland's electrolytic machine is shown here. The overflow from a settling tank carrying fine material in suspension enters a battery at one end near the bottom and flows upwards between the plates. The treatment is practically instantaneous and there is a continuous overflow from the battery to settling tanks where the material in suspension rapidly settles. The area of the electrodes is in direct proportion to the volume of water treated. They may be composed of aluminum, iron or carbon and they may be placed from one-half inch to several inches apart, depending on the conductivity and velocity of flow of the electrolyte. The interior of the battery is insulated with hard rubber to prevent short circuiting. As there is necessarily a slight decomposition of the water, there will also be, over considerable periods of time, a tendency for deposits to build up on the cathode. When this occurs the deposits are dropped by a simple reversion of the poles.

## Marine Boilers, Gold Dredges, and Empire Drills

WHAT are said to be the largest marine boilers ever built in America for the largest ship in the United States Navy are under construction in the plant of the New York Engineering Co., at Yonkers, N. Y. Four boilers have been completed and



BOILER FOR BATTLESHIP MADE BY NEW YORK ENGINEERING CO.

shipped by lighter to the Brooklyn Navy Yard. Under the Navy contract, delivery is not compulsory until July, 1922, but the first delivery has been made eight months in advance of contract requirements. The remaining eight of the order are 80 per cent. finished.

Digitized by Google

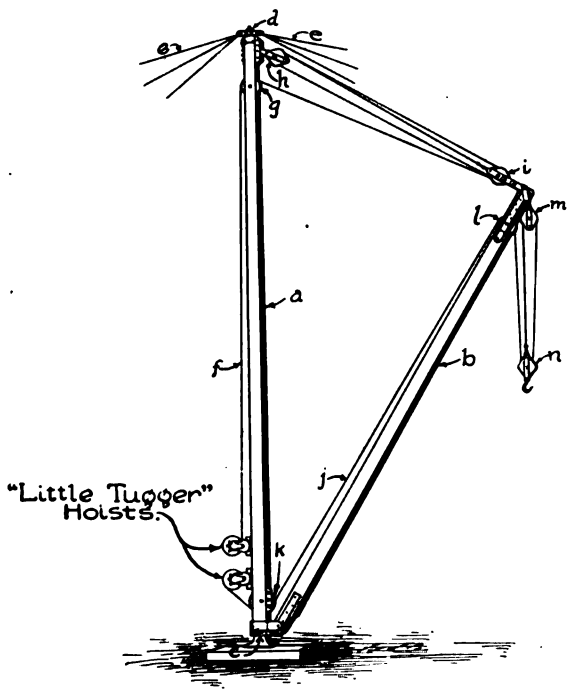
These twelve boilers, known as "The Ludlum Type," will furnish the battleship, if it is not scrapped in the disarmament program, with 90,000 hp. Boilers of this type are also being used by several mining companies in the West.

The New York Engineering Co., of which A. C. Ludlum is president, is better known to the mining profession as builder of gold dredges and the Empire prospecting and sampling drill.

## Little Tugger Derrick

NECESSITY caused the invention of an inexpensive derrick and at the same time showed another use of the Little Tugger hoists, made by Ingersoll-Rand Co.

After a fire which gutted a 600-ton mill, two Little Tugger hoists were used in the construction of the derrick for clearing



LITTLE TUGGER DERRICK.

away the debris to make room for the new mill. This derrick was used in clearing away about 90 per cent. of the wreckage.

The hoists are small, compact drum hoists operated by compressed air or steam, originally used in the company's mines. The mast and the boom were both made from telegraph poles. The mast is carried at the foot by a pivot *d*, held by guy ropes *e*. The boom is pivoted at the lower end of the mast. The rope *f* is connected with the upper hoist and passes over the sheave *g* at the top of the mast and through the pulley *h* at the mast head and *i* at the top of the boom. This rope varies the angle of the boom. The hoisting rope *j* is connected with the lower hoist and passes under the sheave *k* on the mast, over sheave *l* on the boom and through the pulleys *m* and *n*. This is the rope which suspends the load.

The derrick is swung by hand although another Little Tugger, furnished with a bull-wheel, could do this work if it were desired. With the pulley arrangement shown, the derrick is capable of lifting approximately a 3-ton load.

## Industrial Notes

**C. H. Brandes,** formerly chief mechanical engineer and general purchasing agent of the American Metal Co., Ltd., of New York, and its domestic and foreign subsidiaries, has opened offices at 42 Broadway, New York City, for consulting work.

**Hercules Powder Co.** will be glad to send without charge a copy of a paper on Scientific Selection of Explosives for Coal Mining, by N. S. Greensfelder, that was presented at the meeting of the Coal-Mining Institute of America in December. Address Advertising Dept., Hercules Powder Co., Wilmington, Del.

**Combustion Engineering Corpn.,** New York, recently opened two branch offices, one at 216 Latta Arcade, Charlotte, N. C., in charge of T. E. Nott and the other at Seattle, Wash., where Fryer-Barker Co., 1133 Henry Bldg., represents the corporation.

**William Swindell & Brothers,** Pittsburgh, Pa., have established an electric furnace department under the direction of Frank W. Brooke, late vice-president and chief engineer of the Electric Construction Co. of Philadelphia. This department offers the latest design in furnaces for melting steel, gray iron and non-ferrous metals; also a complete line of electric heating furnaces from 30 kw. upwards. A license to operate under the Marsh Patents for the nickel-chromium electric resistance elements has been granted to this firm.

**Bucyrus Company** announces the removal of its New York office to Suite 728, 30 Church St. E. G. Lewis is in charge. Mr. Lewis has been connected with the sales organization of the Bucyrus Company for many years and has had wide experience in railroad and general contracting work in this country and abroad. M. J. Woodhull succeeds Mr. Lewis in charge of the Chicago office, 622 McCormick Building.

E. R. Weber succeeds J. N. Gawthrop at Minneapolis, 1224 McKnight Building. Mr. Gawthrop will join the staff at the New York office.

## Trade Catalogs

**Carbo Steel Products Co.,** 2600 W. 111th St., Chicago, Ill., is again manufacturing Carbo Steel poles.

**Hendrie & Bolthoff Mfg. & Supply Co.,** Denver, Colo.—Pamphlets describing the Bunker Hill Screen and the Allen Vibrating Screen.

**W. S. Rockwell Co.,** 50 Church St., New York.—Bulletin 240. Heat Treatment of Springs with Stationary and Continuous Furnaces. Shows application of principles that must be considered in improving quality and decreasing cost of springs and similar heat-treated products.

**Sullivan Machinery Co.,** Peoples Gas Bldg., Chicago, Ill.—Bulletin 71-G. Air Lift Pumps. A new edition of an old catalog. Gives instructions for use in requesting estimates on installations.

Bulletin 71-F. Displacement Pneumatic Pumps. Describes a new pump intended primarily for handling acids.

Bulletin 70-W. Sullivan Rotators. New edition.

**Mashek Engineering Co.,** 90 West St., New York.—Catalog No. 5, Briquetting Machinery and Plants. A cloth-bound book of 129 pages. The price of the book is $2, but the Mashek Engineering Co. will send the book free of charge to those engaged in coal mining or coal merchandising. About one-half of the book is devoted to briquetting, including lignite, and discusses binders, costs of manufacture and of plants, etc. The remainder of the book gives descriptions and illustrations of the machinery built and of plants erected by the Mashek company.

**Westinghouse Elec. & Mfg. Co.,** E. Pittsburgh, Pa.—Announcement of Westinghouse Merchandising Bureau.

Catalog 7-A. Industrial Lighting Equipment.

Instruction Book 5232. Rectigon Battery Charger Style No. 301860.

Instruction Book 5229. Type F-11. Oil Circuit Breaker (Manually operated).

Instruction Book 5207. Main Roll Drives. A-C and D-C motors.

Catalog 12-A. Safety Switches and Panel Boards

## EDITORIAL

### Producing Capacity

IN GENERAL the mining and manufacturing capacity of the United States is at present greatly overdeveloped and overbuilt. In certain industries, *e.g.*, bituminous coal mining, this was a chronic and characteristic condition even before the war. In other industries it is a consequence of the war. The subject is one of major economic importance. In it are involved the questions of finding other uses for the superfluous capacity, or in default thereof writing it off. Failure to recognize the situation that may exist in an industry in this respect will lead many people to hold on to plant with the hope of realization from it as a going concern long after such hope should be abandoned. This implies that the plants of an industry will be operated only at partial capacity, with consequential inefficiency; that the industry as a whole will be loaded with an exaggerated overhead; and finally that the industry will be maintained in an overmanned condition, with the serious consequence that the personnel as a whole cannot obtain full-time work.

In considering the position of any industry there must obviously be discrimination. Many industries are conducted in numerous stages. Thus, in the production of metals we have first the mine capacity, next the smelting capacity and finally the refining capacity. We may be overbuilt to different degrees in the several stages, or in one stage may perhaps not be overbuilt at all.

It is highly important, of course, to determine what is to be the yardstick for measuring industrial capacity as a whole. Shall it be the pre-war capacity; or the pre-war rate of consumption; or the estimated rate of consumption during the next few years; or what? Without undertaking to answer these questions, it is obvious that anyone speaking in terms of percentages should be careful to describe what he means. Thus, it has been stated frequently of late that the steel works of the United States were operating at only 40 per cent.

Digitized by Google

of their ingot capacity. That was a correct statement, but nevertheless it conveys false ideas; among others, that if the scale of operations is only 40 per cent. the industrial situation must be very bad; furthermore, that if it is very bad, it can be very much better.

In fact, the ingot steel producing capacity of the United States is about 52,500,000 tons per annum, but we are overbuilt in such capacity, there never having been use for so much. The production of ingot steel was about 30,000,000 tons in 1913. An increase commensurate with the gain in population would lead us to expect a consumption of perhaps 33,500,000 tons in 1922. Thus, if we are producing now at the rate of 21,000,000 tons per annum we are indeed at 40 per cent. of total capacity, but we are at nearly 62½ per cent. of *useful* capacity.

Similar conditions prevail in most of our industries. Note is to be taken of the discrimination that I make between *total* capacity and *useful* capacity. In a book on the "Wealth and Income of the American People" that I am soon going to publish I go more fully into this subject and utter the principles that plant is only valuable to the extent that use can be made of it, that such use is in its maximum roughly proportional to the number of workers existing and that owing to various causes, including war stimulations, we have created a surplus of capacity, representing billions of dollars, that must simply be written off. This takes into account that every industry should normally have some surplus capacity in order to take care of peak loads, that a good deal of what is listed as live capacity is old plant naturally approaching the state of obsolescence, and other factors.

The principles to which I have given expression imply the need for a correlated and qualifying factor, *i.e.*, as to the efficiency of workers. The 8,000,000 factory workers of the United States, if fully employed may make in 1923, let us say, a larger or smaller output per person than they did in 1913. When we project probable production and consumption in proportion to population we assume that rates will be maintained. This is a subject in the new field of quantitative economics that has not been explored. We are sure that during the century preceding 1913 the output per worker in the long run increased greatly, which is evinced by the immense improvement in the scale of living among civilized people. We know that this was especially attributable to mind which gave to men the help of machines. As to what man himself did we know next to nothing.

Since 1913 we have had more data on this subject. It is not well coördinated and is far from being enough, wherefore any ideas derivable can be nothing more than hazy. To me the indications point toward a certain impairment in the efficiency of labor during the last 10 years. In other words, the output per worker appears to have declined in spite of increased mechanicalization during this period. While saying this I am fully conscious of the quite different showings in individual industries and also the remarkable change for the better that began right after the middle of 1920. If this idea be correct it does not follow that production and consumption in the years immediately coming will be at the pre-war rate, $a$, plus $x$ per cent., corresponding with increase in population, but it may be ($a + x$ per cent.) 0.95, the last element being merely an illustrative factor representing impairment.

This is, of course, equivalent to indicating a deterioration in the scale of living. I am not sure that just that is not already in evidence. In the matters of housing and transportation it certainly is so. Notwithstanding the automobile, the cinematograph and the phonograph, which are doubtful advantages, and the extension of the telephone and the electric light among our homes, I wonder if the American people as a whole are so comfortable now as they were in 1913?

But returning to my initial subject, it will be evident, I think, that American business did not at the end of 1921 stand at the low ebb of 40 per cent. of normal, or anything like that, but rather was it probably around 80 per cent., if we assume normal to be the pre-war rate plus the natural expansion reasonably to be expected by virtue of growth in population. Any other idea would fly in the face of other basic indications, *e.g.*, the extent of unemployment, as to which fallacies are also propagated.

According to governmental estimates not more than 2,000,000 workers in the United States were idle at the end of 1921 compared with 5,000,000 at the end of 1920. These estimates, however, are very vague and it is doubtful whether they ought to be characterized as being much more than imaginary. If data bearing on this subject from various sources be compared, it will be found that things are not very well in tune.

For example, the Committee on Unemployment Statistics of the Merchants Association of New York found that the number of unemployed in the City of New York at the end of 1921 was 331,000, or about 13 per cent. of the 2,531,747 persons in the city reported by the census as being "gainfully employed" on Jan. 1, 1920. The total number of non-agricultural workers in the United States is about 30,000,000. If the same proportion were everywhere unemployed as in the City of New York the total for the United States would be about 3,900,000. In fact, data from other industrial centers appeared to run around 13 to 15 per cent.

Such figures are in no wise surprising in view of the severity of the economic readjustment that is in progress. In normal times the range between the extremes is probably not more than 10 points. With employment at 95 per cent., business is ordinary. At 98 or 99 per cent., there is a boom. At 90 or 92 per cent., there are what we call hard times. Below 90 per cent. there is an unusual crisis, such as the present.

The business affairs of the United States are on a stupendous scale. With 11 million agricultural workers

Digitized by Google

and 30 million town workers, a pre-war gross income of about 34 billion dollars and an annual living expense of about 27 billion, it is necessary to have a broad perspective if we are going to try to see things as a whole. The affairs of an individual industry, even a big one, may be a good deal out of line without much affecting the general average. In the long run, however, everything is bound to come pretty much to the same plane. The process of getting there is what we call readjustment.

W. R. INGALLS.

## Columbia Mining Scholarship

COLUMBIA University has requested the American Institute of Mining and Metallurgical Engineers to name the recipient of a scholarship in mining or metallurgy in its School of Mines, Engineering and Chemistry. The Columbia School of Mines is now on a three-year course on a graduate basis. The purpose of this advanced course is to turn out a high type of engineer trained in the humanities as well as in the fundamentals of his profession. It is hoped that by placing a scholarship at the disposal of the A. I. M. E., with its membership represented in all the mining regions of the country, there will result a wide-spread interest which will insure the choice of a candidate of the very highest mental and personal qualifications, who will subsequently reflect unusual credit, not only on himself and his alma mater, but also on the Institute whose candidate he would be.

The Woman's Auxiliary of the A. I. M. E. some time ago established an Educational Fund with which to promote engineering education by selecting worthy candidates and assisting them financially to complete their academic studies. The first recipient of this Woman's Auxiliary award was a Montana high school boy who began his college course at the University of California in September, 1921. Gratifying reports of this young man have been received at the end of his first semester.

Because the Auxiliary, as a going concern, had machinery for searching out and nominating a worthy and desirable candidate for this scholarship, the Board of Directors, in accepting the privilege offered by Columbia, put the administration of this scholarship in the hands of a committee with instructions to coöperate with the Woman's Auxiliary, which has now put its machinery at work in all parts of the country looking forward to this nomination. The details of the qualifications and requirements are given in a special article under the report of the Woman's Auxiliary elsewhere in this issue.

The Columbia Scholarship is $350 per year. To this the Woman's Auxiliary has generously added from its own fund $200, so that the scholarship will be worth to the recipient $550 per year. Reappointment of the student to the scholarship for the completion of his course is conditional on maintenance of good standing in his work.

There is no age limit prescribed for the recipient of this benefit. It would not be displeasing to the Board of Award if the successful candidate were an engineer who had already made some progress in his profession and who might, on account of existing business conditions, now have time for advanced work which otherwise he would be unable to undertake.

It is a notable event that the Institute should be asked to administer this scholarship by Columbia University, and it is no less a matter of congratulation that the Institute should have in its Woman's Auxiliary a functioning organism so well able to undertake this work immediately without the usual mental agony and physical discomfort of preliminary organization.

The recipient of this scholarship should be particularly inspired by its source and its association.

PERCY E. BARBOUR.

## Why Retail Prices are High

THE Attorney General has instituted an investigation of the subject of high prices still prevailing for goods at retail, with the intention of explaining, among other things, the wide variation for the same goods in different places, and to ascertain whether profiteering is still going on. The Attorney General does not need to make any investigation of this subject. Both the facts as to existing conditions and the reasons for them are well known. What is needful is not investigation, but the courage to make a plain exposition of the situation.

The prices for many goods at retail are still very high and there are wide differences among them in various places. That is the statement of fact. The reasons are (1) incompetence on the part of retailers and (2) the exorbitance of labor.

In general the retailing of goods in the United States is done in a wasteful way. There are too many retailers in proportion to the population, whose living is necessarily derived from their margin. To a very large extent these are men of small capacity and their costs of distribution are enhanced by the wastefulness of their methods. All of these merchants found themselves at the beginning of the decline with stocks of goods bought at high prices. Rather than take losses they maintained prices with the idea of getting out whole, even at the expense of diminished volume of business.

The other reason for high retail costs is, of course, the high wages that have continued to prevail for labor, which are reflected in high freight rates, high manufacturing costs and high costs of merchandizing and distribution. The farmer of the South sells his cotton at pre-war prices, but the shirts that are made out of his own cotton cost him two or three times what he used to

Digitized by Google

pay. Among the great groups of the nation's workers the farmers have been especially the victims, but great groups among the townworkers have been victimized also.

What is needful in the present juncture is not investigation of anything by the Attorney General, but rather is it educational leadership. There is need for education that will divert the minds of the aggrieved farmers from thoughts of ill-considered agrarian legislation, which is about as useful as the panaceas of old Doctor Swamproot, and turn them toward the true cause of their troubles. When the victimized people and the politicians who represent them cease to be afraid of the labor unions we shall quickly begin to see a change for the better in the matter of retail prices and we shall begin to enter upon the paths of national prosperity.

W. R. INGALLS.

## The Black Future of the Patent Office

MANY mining engineers, mill men, metallurgists, and other members of the Institute are patentees or potential patentees. Besides, the mining and metallurgical industry depends on patented apparatus to carry on its operations. The interests, therefore, which this profession has in an efficient Patent Office are sufficient to warrant personal effort on the part of each member in writing to his Congressmen to urge the early passage of the Lampert Patent Office Relief Bill.

Black as is the immediate outlook for the Patent Office, its future a few months distant seems to promise nothing but complete disorganization. With the industrial activity and progress of the last few years, the work of the Patent Office has been increasing by leaps and bounds. Concurrent with this has been the rise in wages in industry, while the salaries of Patent Office examiners have remained fixed at a rate considered meager many years ago, and the position of patent office examiner, therefore, has become less and less attractive. Resignations have become more frequent, with disastrous results. Not only does it require the repeated training of new men, but it leaves an ineffective and inadequate force which is utterly unable to handle the amount of business in hand. The position of examiner is so unattractive at the present time that the vacancies are not being filled and it is the opinion of people well qualified to judge that if the process of disintegration goes much farther the Patent Office will be stalled.

American Engineering Council, through its Patent Committee, of which Edwin J. Prindle, of New York, is chairman, supported by a large number of other patent lawyers, after a great deal of effort prevailed upon the majority leader in the House, Frank W. Mondell, to call up the Lampert Patent Office Release Bill for immediate action. The difficulty was a stated intention to postpone this legislation until after the passage of the general reclassification of governmental positions. However, success has attended these efforts to the extent of having the bill passed in the House. It must now be passed in the Senate.

The general reclassification bill, even if it should ever become a law, cannot by its terms become effective in less than eighteen months. This delay would be fatal to the Patent Office.

PERCY E. BARBOUR.

## Employment Service to Executives

FOR a number of years the Institute headquarters has taken up with executives of large mining companies and other employers of many men, particularly engineers, the matter of placing as many students as possible at the end of the academic year, so that for those who desired it there would be little interim between the close of their college course and the beginning of their gainful occupation. This service seems to have been much appreciated both by the young men and by the executives.

The Employment Bureau organized by the four national societies, and conducted by their secretaries from the Engineering Societies Building, took over this work but owing to the fact that it is directly under the charge of the four secretaries, it still maintains the intimate membership contact. With the reopening of the country's mines, this Employment Bureau, which now is one of the activities of the Federated American Engineering Societies, finds itself in a particularly fortunate position to furnish to executives of all of these companies any number of engineers, many of them with special attainments. These engineers are so classified that the Bureau can deliver almost anything that is asked for.

Executives and employers of large numbers of engineers are coming more and more to appreciate the value of this Federated American Engineering Service, and the more widely it is used the greater will be its value to all concerned.

PERCY E. BARBOUR.

## Caving Systems of Mining

TWO errors occurred in the article by Mr. J. Parke Channing, in the January number of MINING AND METALLURGY. In the second column on page 7, in the sixth line from the bottom of the column, the fourth word, steep, should be flat, and on page 8, in the third line of the third paragraph, Guy R. Johnson, Sr. should have been J. E. Johnson, Sr.

# Review of the Month

WITH the economic situation of the world what it is, we may expect important events in every month of 1922, and January showed us somewhat of the nature of things that will happen. The Germans announced their inability to meet in full the reparation payments that were due Jan. 15. The Supreme Council arranged a plan for them to pay some thing on account every 10 days, and called a conference at Cannes to talk things over. While this conference was in progress Premier Briand resigned and was succeeded by Poincaré. This emphasized the growing differences between British and French policies and interests. The French want to exact the utmost from the Germans; so do the British. The latter think, however, that the French aims will so cripple the Germans that they can not work properly and hence can not trade. Great Britain, with a huge unemployment problem, must have trade. The French thought that Briand was unduly deferring to the British and withdrew their support of him.

The other important political developments of the month in Europe were the establishment of the Irish Free State, relieving the British of the vexatious Irish question; and the growing tendency to recognize the Soviet government of Russia and admit its representatives into international conferences.

In the United States the great political event was the establishment of the dominance of the agricultural bloc in the Senate, which implies the passage of agrarian legislation that will probably be unwise.

Economically, there was no progress in the United States. If anything there was probably some recession in the physical volume of business. There were some further reductions of wages, but these were irregular, geographically, and moderate in amount. The great unionized trades maintained the jam. Events of great importance were the formal demand of the anthracite coal miners for increased wages on April 1 and the declaration of the bituminous coal miners that they would resist a reduction at that time. The attitude of these groups is believed to presage labor troubles in the spring.

In the metal markets affairs were dull during January, but prices were generally firm, save for a little further weakening in iron and steel. In the matter of production, however, there was some quickening of activity, especially in copper, zinc and iron.

The mining companies of Butte which had been idle began work on Jan. 16, preparatory to resuming production. All of the companies in the district joined in an agreement to reduce mine, mill and smelter labor 50c. per shift, making $4.25 the basic wage for miners. Anaconda reopened four of its mines. Butte & Superior is now to ship zinc concentrates to the Anaconda electrolytic plant at Great Falls. The lixiviation residues from that plant will go to the East Helena plant of the American Smelting and Refining Co.

Mining operations were gradually increased on the Minnesota iron ranges, unemployment being thereby considerably relieved. There was also an increase in the scale of operations in the Tri-State zinc district.

New freight rates on lead bullion and other smelted products from Tacoma, Kellogg, Northport, and East Helena were approved by the Interstate Commerce Commission and announced as effective Jan. 5, 1922. The new rates are as follows:

| | |
|---|---|
| To Pittsburgh | $13.25 |
| Cleveland | 13.25 |
| Indianapolis | 12.75 |
| Chicago | 12.00 |
| St. Louis | 11.40 |
| Kansas City and Omaha | 10.80 |
| St. Paul, Minneapolis and Duluth | 9.00 |

The rate from Northwestern smelting points to New York remained unchanged at $16.50.

Wage reductions by the smelters in Utah were announced about the middle of the month. Sporadic readjustments were effected elsewhere. On Jan. 1, 1922, the Porcupine mining companies reduced wages approximately 50c. per day. This gives to drill runners $4.75 per day, which is 25c. higher than the Cobalt scale.

In coal mining, conditions continued to be bad owing to the stubborn resistance of the union miners to any modification of the existing wage scale. On this basis many operators could not sell coal at all, with the result that their miners had high wage rates but no income. More and more was the necessary coal supplied by the mines of those fields where the open shop prevails.

A plan for reorganizing the Ray Hercules Copper Co. was announced. The new company will be known as the Ray Hercules Mines Incorporated and will have an authorized capital of $1,000,000 in first mortgage 6 per cent. bonds and 1,200,000 shares of stock of $5 par value.

A general strike of labor in the gold and coal mines of the Transvaal began on Jan. 14. The Federation of Workers (the labor union) complained that non-union workers were being employed and there is dispute over some conditions connected with the employment of native labor. The strike was precipitated through an attempt by the mining companies to reorganize their working forces by greater employment of native labor, particularly in the semi-skilled occupations, in order to decrease working costs.

The Spanish Government announced the conclusion of the contract with the Rothschilds of London for the sale of the Almaden and Arrayanes quicksilver, which henceforth will be marketed by the government itself.

## The Ratio Between Labor and Output in Mining

By William Kelly

IT IS customary to express the ratio between labor and output in mining as tons per man. Thus, if there are 300 men working at a mine and the output for a day is 600 tons, it is usual to say that the output is 2 tons per man. Let us suppose that of the 300 men, 100 are on surface with an average wage of $3.10 a day, 80 are underground laborers and bosses averaging $3.50 a day and 120 are miners breaking ore at $4 a day. The average of all the wage rates would be $3.566 per day. To find the labor cost from these data, the total number of men must be multiplied by the average of their wages and divided by the output. In this case, it would be 300 × $3.566 ÷ 600 = $1.783.

A more rational method of expressing the ratio between labor and output is the inverse of the above, namely, labor per ton. Thus, in the case cited, 600 tons were produced by 300 men or 0.5 days work per ton. This method lends itself readily to subdivision between different classes of labor and the relative cost per ton of each; thus, with an output of 600 tons there would be as above:

| | No. Men | Labor per Ton | Average Wages | Cost Per Ton |
|---|---|---|---|---|
| Miners | 120 | 0.200 | $4.00 | $0.80 |
| Underground labor | 80 | 0.133 | 3.50 | 0.467 |
| Surface labor | 100 | 0.167 | 3.10 | 0.516 |
| Total | 300 | 0.500 | $3.566 | $1.783 |

The subdivisions can be carried out for other classes of labor—trammers, timbermen, hoisting engineers, shop men—as desired and, with the average wages of the class, these elements of the cost can be computed easily.

On the same basis of wages, unless there are radical changes in the character of the operations, the average wages are not likely to vary more than a cent or two from month to month and, though the daily variations are more than this, the general average of wages will give results sufficiently close for daily comparisons.

To compare the efficiency of work under different wages scales or the results obtained at different mines, the wage rates and cost per ton must be disregarded and the comparison made either on the basis of tons per man or labor per ton. While the tons per man may suffice for the total result, it does not show well the relation of the different parts of the work. Thus in the example used, the tons per man for miners is 5, for underground labor is 7.5, for surface labor is 6, and for all classes is 2, but these figures give us no idea of the proportionate part of the work done by the different classes of labor. In comparing the results at different mines or at the same mine under changed conditions, it is difficult to draw conclusions from such figures. Expressing the ratio in labor per ton not only gives total results, which are comparable, but the figures may also be used to show the proportion between the different classes of work. To be consistent, if figures are carried in tons per man, the cost should be figured as tons per dollar.

## Personnel Research Federation

THE first annual meeting of the Personnel Research Federation was held in the National Research Council building, Nov. 21, 1921. The membership was increased from 8 to 24. Approximately 50 representatives were present from industrial establishments, colleges, universities, American Federation of Labor, U. S. Government bureaus, personnel research organizations, Engineering Foundation and several divisions of National Research Council.

During the all-day meeting, addresses were made by Chairman Yerkes, Vice-Chairman Gompers (read by Mr. Matthew Woll), and Secretary Flinn; Dr. J. David Thompson, on behalf of Commissioner of Labor Statistics Stewart, presented advance copies of *Bulletin* 299, of the Bureau, entitled "Personnel Research Agencies." Valuable papers were read by C. S. Yoakum, director Bureau of Personnel Research, Carnegie Institute of Technology, Pittsburgh; Joseph W. Hayes, of the Scott Co.; L. L. Thurstone, of the Carnegie Institute of Technology; Miss Anna Bezanson, of the Wharton School of Commerce, University of Pennsylvania. Officers were elected as follows:

Chairman—Robert M. Yerkes, National Research Council;
Vice-chairman—Samuel Gompers, American Federation of Labor;
Secretary—Alfred D. Flinn, Engineering Foundation;
Treasurer—Robert W. Bruere, Bureau of Industrial Research;
Director—Columbia University.

## Standardization of Wood-testing Methods

THE American Society for Testing Materials and the U. S. Forest Service have been designated by the American Engineering Standards Committee as joint sponsors for the development of uniform standard methods of testing wood. This action was taken after a canvass of the principal national bodies concerned with the proposed project, from which it was apparent that there is a real demand for the work, and that the joint sponsorship here indicated would be acceptable to the industry.

# British Oil Policy in Foreign Fields

By SIR JOHN CADMAN

President of the Institution of Mining Engineers of Great Britain

IN THE changed circumstances which now confront the world, an international open-door policy is the only way to keep pace with the world's demand for oil. You may rest assured that as far as the British Empire is concerned, American capital for the development of oil resources is welcome, and little obstruction will be found in the way to permit the use of foreign capital in the group of countries which constitute the British Empire.

In the war days we worked in close coöperation and harmony, but in disbandment of the Petroleum War Service Committee, when the war ended, I feel that it left its task unfinished. In the wake of war there appeared a ghost of war-time conditions in the form of belief that Great Britain was straining to corner the petroleum resources of the world. I am certain that if the war-service committee had continued its work in the period of reconstruction the real story would be known and this sinister ghost would have long since vanished before the truth.

### Great Britain Not in the Oil Business

With respect to the three most misleading fallacies about Great Britain's oil policy, I cannot emphasize too strongly the following facts:

1. *It is not true* that the British Government is engaged in the oil business and controls the Anglo-Persian and Royal-Dutch companies.

2. *It is not true* that Great Britain is trying to secure a monopoly of the petroleum resources of the world.

3. *It is not true* that Great Britain is shutting out American citizens and American capital.

Let me tell you briefly what is the truth about these matters:

One is led to believe that the British Government is a great oil company, and that it has as its subsidiaries such companies as the Royal Dutch Shell and Anglo-Persian companies. Rumor asks you whether you can afford to become dependent for even a portion of your crude petroleum upon such a British oil corporation, and especially upon a great Anglo-Persian-Royal-Dutch-Shell combine. You are asked to believe that within a few years your own internal source of supply will be exhausted.

Emphatically, the British Government is not in the oil business. She does not control the Royal Dutch Shell—she does not have a single share in that corporation, which is controlled by foreigners—and with the exception of holding shares in the Anglo-Persian Oil Co., the British Government is not interested in oil companies, and certainly has no control over the commercial management of the Anglo-Persian Oil Co.

The Anglo-Persian Oil Co., with which I am associated, was formed in 1909 to take over and exploit certain concessions which had been acquired in 1901 by a Mr. D'Arcy. After an up-hill fight, the company met with a certain measure of success, and, in 1913, acquired additional capital to carry on its work.

### Investigated Source of Supply Before Making Contract

At this period money was not easy to procure for oil ventures. An attempt was made to sell to the British Naval Department a certain supply of fuel oil and to secure payment in advance. It was necessary for the Naval Department to assure itself that the supply of oil would be forthcoming before agreeing to any such payment; and with this object in view a small Naval Commission was sent to Persia to investigate the source of supply. I happened to be one of the technical members of the commission.

The result of the inquiry was satisfactory and the terms of the contract agreed upon. It then became necessary to find some security for the financial advances to be made, and the plan was hit upon of increasing the capital of the company and allotting to the British Treasury ordinary shares for these funds. Two Government directors were appointed to the board, but it was agreed that these directors were not to interfere in any shape or form with the commercial policy or management of the company.

### Government an Ordinary Shareholder

This arrangement was made in 1914 and the position is the same today. The Government still has its contract for fuel oil with the company, is still an ordinary shareholder, but has no voice in the management of the company. The reason for this arrangement was a full recognition by both sides of the inadvisability of Government trading, and the inability of the Government to properly administer a commercial concern.

I cannot help feeling, however, that the company has suffered from the presence of its sleeping partners, by the inference, which is wholly incorrect, that the Government exercises an influence over the commercial affairs of the company. The operations of the com-

Digitized by Google

pany have been very successful, but these have been achieved not because of, but in spite of, the Government holding.

Great Britain consumed the greater part of the petroleum products sent over by America during the war and was ever crying for more and more oil. The demand for oil and the high price have attracted British companies to greater endeavor to find oil, but many of these companies are more interested in selling stock than in finding oil.

Years ago, when great distributing companies pursued a policy of selling their own oil and not producing, an impression arose that such companies endeavored to shut off new sources of supply, such as Burma and Trinidad, and for that reason certain measures of assistance were afforded independent British companies. As a matter of fact, the protection of independents in certain parts of the British Empire was even less drastic than the Sherman and similar laws in America.

Since the war, the whole petroleum picture has changed. Your own supplies no longer enable you to meet the great demand for the home market and it is not unnatural that you should proceed at once to explore foreign sources of supply. American companies, anxious to go abroad and develop petroleum resources, will find that while the group of countries which constitute the British Empire subscribe their own conditions, the British people welcome American capital; the door is open, in fact a very open door with few exceptions, and where there are now restrictions, they will soon be removed.

A weird picture has also been drawn about Mesopotamia. The fact is that the ownership of the oil deposits in Mesopotamia will be secured to the Arab state as part of the administrative arrangements under the treaty mandate. The interests of the Arab state will be carefully safeguarded. That is the first charge upon the Government that is to exercise this mandate. It must also be realized that due consideration will have to be given to rights legally secured before the war and that any such rights can be considered only when the new government is set up.

Great Britain is denying the opportunity to all nationals, her own included, to make any superficial examination of these areas for commercial purposes until such time as she has been definitely charged with the mandate.

Beyond that it has been stated that in the San Remo agreement, Great Britain and France have parcelled out Mesopotamia between themselves. As one of the signatories of that agreement, I can assure you that there was nothing in the minds of the framers that was against the interest of the United States or any other country. In no part of that agreement is there a suggestion of discrimination, nor was it the intention to discriminate against any similar reciprocal arrangement with any other country. Its principal object was to secure an arrangement that would be of lasting benefit to the Arab state when constituted, which could not be secured under any other arrangement.

We in Great Britain feel the same way about the Government in business as you do in the United States. If I were to tell you the story of the British Government's attempt to manage industries during and subsequent to the war, particularly with regard to coal and the railroads, I should relate a very sordid tale. The British public has had enough of Government interference with commercial affairs to last for a life time, and any person who tried to get a seat in the House of Commons on such a platform would be doomed to the bottom of the poll. If there is any suggestion that your government should take a direct interest in your oil industry, I trust you will give thought to the recent experience of government control in Great Britain.

The petroleum industry in its present highly developed state requires the integrity and capacity of the great leaders of industry—men who have been trained in business and technique and for whom political service holds no attraction. I think the lesson which the petroleum industry has learned out of its war experience is to realize fully its responsibility to the public, if it is to enjoy freedom from Government control or interference.

The solution lies within the industry itself, by getting together to promote its welfare by common consent of its members and by coöperating in every possible way. The work that has already been done in the United States is a model which other countries may well try to emulate and international coöperation between such organizations will then become possible and effective.

What the world wants as much as anything is cheap power. We can realize success in the great project which lies before us all in close coöperation and the resumption of those high ideals which prompted such harmonious and satisfactory partnership during the war.

---

## War Department Using A.E.S.C. Standards

THE Secretary of War has directed that the supply branches of the army utilize, in connection with their specifications, the standards that have been or may be adopted by the American Engineering Standards Committee.

"The importance of standardization of war supplies cannot be exaggerated," said Colonel George S. Gibbs, of the General Staff, in a recent address before the American Mining Congress. "In these days war involves the united effort of an entire nation and the combined employment of all of its principal industries.

"It requires no imagination to see how tremendously both the business and military interests of the War Department can be assisted by standardization. It may be safely predicted that business firms dealing with the War Department will find a steady and gratifying improvement in the clearness and simplicity of its requirements."

# Present and Future of the Copper Industry

By CORNELIUS F. KELLEY

President, Anaconda Copper Mining Company

I HAVE been asked to discuss "What Can be Done to Revive the Mining Industry," particularly from the standpoint of the copper industry. It is impossible to consider this problem, if in fact there can be one, from an isolated position. The mining industry is but a part, although a very important one, of that exceedingly complicated machine characterized as commerce, which comprises within its operation and functions the multitudinous activities that, combined, make up the sum total of the production, manufacture, distribution, sale and utilization of goods and products resulting from the agrarian, industrial and commercial effort of mankind.

We survey a world today with its disturbed mass of humanity permeated with discontent, passions loosened by brutal combat not yet brought under control, class hatreds aroused, national prejudices in a state of stimulated excitement, governments for the most part enfeebled, some destroyed to their foundations, with fragile structures raised in place of those that seemed enduring, and which have disappeared. A burden of indebtedness incurred in defiance of all economic law exists, to meet the exactions of which, levies of taxation that constitute a grievous burden upon effort and industry are exacted by the needs of those nations that are most favored, while printing presses are busy manufacturing currency that either has, or approaches, a negative value among those less favored. This picture, while not pleasant, is one that should be looked at squarely and carefully appraised in estimating the immediate future.

For four years the world marshalled, and exerted without stint, its combined endurance, vitality and resource in an effort of destruction, which violated no less the orderly working of physical and economic laws than it did the conventions of social and civic relations. To have imagined that without travail the orderly processes that governed the relations of mankind could at once be reestablished and begin functioning, was, as has been demonstrated, fallacious; perhaps no more so than the error that is committed today by those opportunists who fail to take cognizance of basic conditions which must be remedied before the world can resume its progress to a universally prosperous and satisfactory condition.

Please do not gather from this somewhat unpleasant recital that I regard the future with gloomy foreboding or entertain pessimistic doubts, for, emphatically, I do not.

* Address at meeting of New York Local Section, Dec. 7, 1921.

While the magnitude of the disaster that has over taken the world is greater than any that has occurred before, and the disarrangement more complete than in any previous experience, the student of history knows that the difference lies largely in the extent of the damage and the difficulty of repair. Progress has been checked, not stopped; prosperity impaired, not destroyed. Civilization has suffered a grievous wound, but its ultimate destiny is coexistent with the instinct of progress in the human race.

These general observations have been induced as a foundation for the assertion that the revival of prosperity in the mining industry, particularly in the copper business, is not a topic of isolated consideration, apart from the larger aspect of the world's industrial and financial status. It must be viewed from its proper relation to the world's business, and while we no doubt have problems that are particular to our industry, which we must solve in order to realize for it the greatest prosperity to which it can attain, we cannot disregard the effect of economic forces of world-wide influence, and hope, as do some, according to attributed declarations, that we can lift ourselves up by the bootstraps into the sun of a beneficent prosperity while depression hangs like a mist enshrouding other cognate and related activities.

## The World, and Therefore the Copper Industry, Will Inevitably Progress

Sooner or later, the idea that political action alone can remedy existing economic conditions will be abandoned. The truth of the law of gravity will be reestablished and serious attention will be paid to the subject, now somewhat obscured by the pageantry of current events, that the fundamental problems of the cost of production and the facility with which commodities representing the wealth of the world can be transported and distributed from sources of origin to points of distribution and consumption, are important factors in the situation.

At this critical juncture in the world's history, one must either take the position that the world is going to make progress, or that it is going to retrogress. That the latter course is its destiny is inconceivable to the normal mind. It is contrary to the dictates of religion, history, experience and common sense.

In physics, we were taught the laws of the composition of concurrent forces, and the truths derived from

Digitized by Google

such study have application in finance and industry. Granting that there must be a composition of forces which at the moment seem conflicting, and to the timid presage disaster, the inevitable result will be along the line of progress, and if so, there can be no doubt of the future of the mining industry, particularly that branch devoted to copper mining and manufacture.

If you are a bull on the future of the world, then be a bull on the copper industry. If you are unwilling to hazard a conviction that the world is to go ahead, there is no reason why you should have a conviction about anything; and more particularly, there is little reason why such a conviction should be of interest to anybody.

The foregoing assumes that there is nothing inherently wrong with the copper industry aside from the extent to which it is involved in a world-wide situation. Is this assumption susceptible of demonstration?

It would be interesting, in support of our text, to trace the development of the industry from its early beginnings when sailing vessels bound from Chile around the Horn to Europe found it profitable to deviate from their course to drop a few copper bars at Baltimore to supply the small demand of a country that had then developed no domestic supply of the metal; or to follow, from its initiation in the Naugatuck Valley, the development of a modest effort to manufacture brass buttons, then a common article of utility and adornment, which has brought about the gigantic industry of mining, metallurgy and manufacturing of copper and copper products as it exists today; but for the present purpose it is unnecessary to do so.

The story is a record of achievement. It embodies the romance of the Western pioneer with the ingenuity of the Yankee manufacture. It is a factor concurrent with the progress of the last half century, and symbolized, and to a great extent controlled, the turning of the world from the direct agency of steam to the more potent, facile and economically applied force of electricity as a motive and communicating agent.

To appraise intelligently the situation today, it is only necessary to scan the industry for a period of 20 years. This period, brief in time, has been epochal in accomplishment, for during it the production of ore, beneficiation of its contents and consumption of the product, outstripped all previous periods and established a record that rivals the achievement in any other line of industrial effort.

The war, with the accompanying necessity for metal for munition purposes, completely dislocated the industry and while apparently giving it a temporary prosperity, resulted in seriously impairing its status.

The world's production of copper in 1900 was approximately one billion pounds. The *Engineering and Mining Journal* published an output of 1,093,115,320 lb.; the Geological Survey, 1,089,984,000 lb. Of this total output, the production of the United States was approximately 55 per cent. The same authorities published respectively, 600,832,960 lb. and 606,117,166 lb. as the proportion of this country's production to the whole.

The succeeding decade was marked by an extraordinary increase in production, due generally to bringing into operating activity the low-grade copper deposits, known as the porphyries, capable of making a large output upon a relatively small capital investment and at a comparatively low cost.

In 1912, the world's production had increased to 2,240,246,177 lb., and that of the United States to 1,243,268,720 lb., an increase above the output of 1900, in both foreign and domestic, of about 100 per cent. The percentage of domestic production remained about 55 per cent. The peak of the world's production was reached in 1917, with an output of 3,137,659,472 lb., of which 1,886,120,721 lb., or 60 per cent., was domestic. The peak of the United States production occurred in 1916, when an output was reached of 1,927,850,548 lb., or 62.7 per cent., of a total of 3,070,930,639 lb. for that year.

It is interesting to note that while the world's production has increased, from 1900, a maximum of about 187 per cent., and that of the United States a maximum of 218 per cent., the proportion maintained between domestic and foreign production has been fairly constant, on a percentage basis, to wit: 55.6 per cent. in 1900, a maximum proportion of 62.7 per cent. in 1916, and 62.3 per cent. in 1920.

Any survey of the copper industry must look at this large increase of production squarely, and no forecast that attempts either to disregard or minimize its impor-

Digitized by Google

tance can find acceptance by those who give the matter intelligent consideration. Conversely, production data in themselves mean little, for to draw a conclusion from the increase above cited, without further study, would be to measure its consequence from a standpoint that disregarded the changes that have occurred in consumptive demand, actual or potential, during the period under discussion.

It is interesting to note, for the purpose of gaining an impression from comparative statistics, the relative increase in the production of some other basic commodities during the same 20-year period.

Table 1 shows the production in 1900, 1912 and the peak production within that time, of a few basic commodities.

TABLE 2.—*Estimated Consumption of Copper in the United States*

| | 1919 | | 1920 | |
|---|---|---|---|---|
| | Pounds | Per Cent. | Pounds | Per Cent. |
| Electrical manufactures | 284,000,000 | 23.48 | 340,000,000 | 26.12 |

| Fire extinguishers | 2,000,000 | 0.16 | 2,100,000 | 0.16 |
| Pins | 2,000,000 | 0.16 | 2,000,000 | 0.15 |
| Valves | 10,000,000 | 0.83 | 10,000,000 | 0.77 |
| Coins | 2,075,321 | 0.17 | 3,148,863 | 0.24 |
| Bearing metal—steam railways | 45,000,000 | 3.72 | 45,000,000 | 3.46 |
| Cash registers | 1,300,000 | 0.11 | 1,340,000 | 0.10 |
| Condensers | 10,000,000 | 0.83 | 6,000,000 | 0.46 |
| Miscellaneous | 150,000,000 | 12.40 | 180,000,000 | 13.83 |
| Total | 1,051,763,764 | 86.94 | 1,137,435,538 | 87.37 |
| Exported in manufactures | 157,965,641 | 13.06 | 164,420,412 | 12.63 |
| Total in manufactures | 1,209,729,405 | 100.00 | 1,301,855,950 | 100.00 |

The impression that one obtains from these statistics is that the increase in the production of copper has not been disproportionately large as compared to that of other commodities, particularly when consideration is given to the industries in which the product finds its ultimate utilization.

There is no doubt that during the war years production was stimulated to an output exceeding an economic maximum, and that copper was largely diverted from lines which if developed would have produced an increased consumptive demand. It is likewise true that the variety and essential character of the industries where copper is used are the best guarantees of the future.

As indicative of the ultimate uses of copper, estimates of consumptive demand in the United States for the years 1919 and 1920 are submitted in Table 2. The conclusion that follows inevitably from the foregoing summary is that if the world is to progress along the most required lines, and no other premise can be assumed as the basis of industrial effort, the variety of the markets available for copper listed here compares favorably with those available to any other commodity.

Electrification of the world will continue to advance, particularly along the lines of communication and transportation. The building industry must meet the requirement of housing the people of the world and their activities. An industry of which the prosperity is assured by the progress that must be made along these lines finds itself in a particularly favored position as to its comparative position upon a resumption of normal conditions.

Since the signing of the Armistice, the copper industry has suffered critically, but it is my conviction that the day of its greatest travail has passed. Completely dislocated by war demand, operated practically as a Government adjunct during our participation in the war, required to maintain a production that the producers felt, after the first six months of 1918, was unwarranted and constituted a menace to the industry, the abrupt termination of war demand completed the demoralization of the industry, which found itself with a stock of copper that must be marketed before an economically sound basis could be reestablished. No industry has been more completely liquidated, and no industry is in a better position today to go forward, provided the world itself is to move in that direction.

On Jan. 1, 1919, the stock of copper, according to the best available statistics, assumed the unprecedented total of 2,278,812,300 lb., made up as follows:

| | Copper, Pounds |
|---|---|
| Producers | |
| Crude | 340,314,000 |
| Process | 319,196,000 |
| Refined | 180,000,000 |
| Total | 839,510,000 |
| Governments | |
| United States | 128,714,200 |
| Great Britain | 179,200,000 |
| France | 168,000,000 |
| Italy | 67,200,000 |
| Germany | 67,200,000 |
| Japan | 20,160,000 |
| Total | 630,474,200 |
| Scrap, in Brass, etc. | |
| United States | 92,028,100 |
| Great Britain | 369,600,000 |
| France | 224,000,000 |
| Italy | 44,800,000 |
| Germany | 67,200,000 |
| Japan | 11,200,000 |
| Total | 808,828,100 |

to which amount, in order to bring the situation to the beginning of 1921, there should be added the production of 1919 and 1920, respectively, as follows:

| | 1919 | 1920 |
|---|---|---|
| United States | 1,310,972,580 | 1,343,945,000 |
| Others | 809,909,940 | 813,893,230 |
| Total | 2,120,882,520 | 2,157,838,230 |

Digitized by Google

or a total, for the two years, of 4,278,720,750, which, added to the stock of Jan. 1, 1919, gives a total of 6,557,533,050 lb. to account for.

The stocks on hand Jan. 1, 1921, have been estimated at 1,764,632,540 lb. made up as follows:

| | Copper, Pounds |
|---|---|
| Producers | |
| Crude | 300,550,000 |
| Process | 229,002,000 |
| Refined | 641,474,000 |
| Total | 1,171,026,000 |
| Governments | |
| United States | 14,158,520 |
| Great Britain | 26,087,040 |
| France | 12,658,240 |
| Italy | 58,240,000 |
| Japan | 73,136,000 |
| Total | 184,279,800 |
| Scrap, in Brass, etc. | |
| United States | 10,606,740 |
| Great Britain | 302,400,000 |
| France | 67,200,000 |
| Italy | 29,120,000 |
| Total | 409,326,740 |

The difference between the above 6,557,533,050 lb. and 1,764,632,540 lb. equals 4,792,900,510 lb., an indicated average consumption for the years 1919 and 1920, respectively, of 2,396,450,255 lb. This is an amount greater than the entire copper industry ever produced prior to the year 1915, and if during the years 1919 and 1920, the world, with the far from normal export demand that existed, actually furnished a market for more than 2,300,000,000 lb. of copper annually, instead of there being any cause for pessimism, the facts should be regarded as a conclusive demonstration of the basic soundness of the industry, for there can be no doubt that during the years of 1916, 1917 and 1918, production was forced beyond a normal economic maximum, and upon a resumption of normal business, the difference between the demand of 1919 and 1920 and that which should ensue will furnish a market for the normal maximum economic output that the industry can furnish.

During the two years above analyzed, it is estimated that the producers furnished, from current production, 3,947,204,750 lb., and that from Government stocks and scrap, brass, etc., a total of 446,194,400 and 399,501,360 lb., respectively, were obtained.

This brings us to a consideration of the present status of the industry. Actual statistics are not yet available, but it is well known that the great part of Government stocks and scrap metals have been liquidated. Stocks in hands of producers have decreased with satisfying rapidity, until the close of the year finds the metal in a fair statistical position, most reliable estimates placing total of all copper at smelters and refineries, in blister, process or refined form, at about 850,000,000 lb. The greater part, approximately, 550,000,000 lb., is refined. This is somewhat more than should be carried under normal conditions and tends to obscure the actual situation. Probably more than one-third of this amount has already been sold for future delivery, without considering the sale to the Copper Export Association for shipment abroad. The remainder, supplemented by current production from the few properties now operating, can meet even the present demand for only a few months—and what then?

Consumption in 1919 and 1920 averaged practically 200,000,000 lb. per month. The sales for the last quarter will average about 140,000,000 lb. per month. The decrease in stock, after taking in current production, would be more than 70,000,000 lb. per month. It takes, under favorable conditions, three months, on an average, for copper in the mine to be put in marketable form as refined electrolytic copper. This means that when the industry is under way and running smoothly, assuming a market demand of 150,000,000 lb. per month, 450,000,000 lb. of copper will have to be mined to fill up the reservoir from mine to mill to smelter to refinery, including working stocks on hand, before any copper from the mines now down is available for the fabricator. As a matter of fact, how long it will take to reach a reasonable output, no one can say. An assumption that in three months there can be a perpendicular increase is unwarranted, for this will differ with the locality and character of the individual operation.

It is not desirable that there should be any shortage of copper available for manufacture, any more than that the industry ever again should face an accumulation of stocks such as resulted from an effort to meet a war necessity; when the risk of accumulation was known, but when national existence was at stake. Industrial risks did not and could not count.

The copper industry will come into its own again, and that speedily, when business resumes. There has been, under the conditions, a demand out of proportion for that of other commodities. The exports for the year will show 65 per cent. of a pre-war maximum; the domestic consumption, 90 per cent. Under these conditions, let us take heart. Civilization will soon be calling on the miner to pick up his tools, and we shall be on our way to the activity and prosperity we so eagerly anticipate.

## License Laws in the Library

THE Engineering Societies Library is making a collection of all laws on licensing, so that they may be available for consultation and research by both resident and non-resident members. Members are requested, therefore, to send to the Library copies of new laws as they are passed or other documents which are not published, to be put on file with the collection.

# Readjustment in the Coal Industry*

By T. H. WATKINS

President, Pennsylvania Coal & Coke Corporation

COAL is the basis upon which the activities of the industrial nations of the world rest today. In order that the coal industry may be restored to a reasonably healthy condition, it is essential that both the operator and the miner should understand that they are directly concerned and that their selfish interests demand that they take an active, intelligent, self-sacrificing view of the entire situation and do their part in restoring and repairing the economic structure. Foreign credits, foreign debts, unstable exchanges, destroyed markets, and inability through lack of credit to carry on as before, all require our attention and coöperation.

### Deep Concern as to Future

There is deep concern as to the future and a realization on the part of some of these leaders of industry that they will have to sacrifice their personal time, away from their desks and the details of business, in order to coöperate with other groups in studying the situation and endeavoring to find the best method of utilizing their knowledge in improving conditions and averting further disaster. It is most unfortunate for the country and for labor itself that the labor chiefs are blind to these necessities, and hostile to every effort to secure their coöperation in rebuilding prosperity.

One factor stands out clearly, *i.e.*, that during the war and after the war, until the collapse that occurred a year ago, the country as a whole was on a false basis. We were nearly all deceived and went blindly ahead in a vicious circle to which speculation, profiteering, wage advances, transportation rates and government experiments all contributed. In certain lines, great progress has been made towards a proper readjustment. Profits, unfortunately, in many industries have disappeared entirely; in others, margins have been cut so close that there is not an adequate return for capital. Capital is timid and, after the disastrous experience it has just gone through, hesitates to invest in anything except underlying, safe securities. We see our government securities advancing; we see good mortgages, good underlying bonds, advancing, but we do not see the credit of our railroads restored. We do not see capital seeking investment in the coal industry, or in the copper industry, or in the steel and iron industry; all of these are over-developed, and it will be many years before the demand catches up with the capacity of the mines, the mills and the factories, the productive capacities of which were so largely increased because of temporary demands of war.

This country used and shipped to Europe 50,000,000 tons of steel for war purposes. The industrial and domestic demand will not take care of more than 50 to 60 per cent. of the capacity of these great iron and steel plants. Coal mines, many of which were opened to take care of the abnormal demand, are now without a market for more than 60 to 70 per cent. of their capacity; the return to normalcy will be slow, but it will come more quickly when we fully understand that the only secure basis of a real prosperity is work and thrift.

We have had on our railroads, in our coal mines, and in many other industries, men who are leaders of men and heads of unions, together with a lot of theorists, preaching that all such sentiments as I have expressed are fallacious and unsound and that they are inspired by an utterly selfish group. They will not credit the great men who have helped build up the wonderful industrial development of this country with any humane instincts, or any desire to be fair, but say that it is a deliberately thought-out conspiracy to break up the unions and pauperize labor.

### Leader of Radical Propaganda

The president of the United Mine Workers of America, an organization claiming to have a membership of over 500,000, is one of the leaders in this radical propaganda. He is recently quoted as saying:

> The cruel theory held by a minority of employers in the United States that the worker should be forced to labor for the smallest possible wage that can be forced upon him is the theory that has caused the greatest and bitterest struggles between capital and labor.
>
> While the number of such employers is small they are largely men who are in control of the gigantic manufacturing and producing corporations of America that give employment to scores of thousands. They stand together under that dire banner, "Lower Wages and Higher Profits," a slogan that openly asserts their right, or might, to seize from both producer and consumer."

The condition in which we find ourselves today was foreseen by far-sighted men a year or more before the crash came, but all of their efforts to point out the dangers confronting us were ignored as completely as were the warnings of the men who predicted that Germany was prèparing for war two years before hostilities commenced.

Bituminous coal and its transportation and consumption are affected directly and immediately by the

*Address at meeting of New York Local Section, Dec. 7, 1921.

Digitized by Google

changes occurring in our business activities. Approximate figures show that 13 per cent. of the production of bituminous coal is used for domestic purposes; about 28 per cent. by our steam railroads; 12½ per cent. by public utilities; about 12 per cent. for export and bunker trade; 15 per cent. in the steel industry; and 19½ per cent. for general manufacturing.

Approximate figures show that 43 per cent. of this coal consumption is in the summer months, from April 1 to Oct. 1, leaving 57 per cent. for the winter, but, on account of the stocking up in summer months, and taking the country's production as a whole, statistics show that for the past eight years 49 per cent. of the total coal has been produced during the summer months. This shows that there has been less intermittency of employment than in any other industry. In other words, the miners as a whole have not suffered as much from lack of work through this depression as the men employed in the steel and iron industry and in other important lines of manufacture. It is estimated, however, that with the more efficient mines of the country actively employed throughout the year, the demand for coal could be supplied with from 150,000 to 200,000 fewer men.

### Advantage of Carrying Coal Stock

If a scheme could be devised by which buyers and consumers of coal could be convinced of a stable market and a regular supply, they would unquestionably carry reasonable stocks, avoiding excessive stocking up at times for fear of strikes, avoiding at other times the depletion of their reserves, and a very important part of the intermittency of employment would be avoided; the burden of carrying this excessive man power would be relieved and those men would be free to go to other occupations.

There is something fundamentally wrong when 30 per cent. of an overload of labor is carried by such a great industry. The miners' leaders realize this to a certain extent, but, in my judgment, have an absurd or dangerous suggestion or demand, as expressed in their last annual convention, for the correction of it, *i.e.*, a six-hour day and a five-day week working schedule. Not only would their suggestion continue the overburden, but it would disturb and disrupt every other line of industry.

The work of those employed in and about the mines in mining, handling, transporting and preparing coal, is not of such a character as to require that they be put in a special class. It is quite true that there are dangers in this occupation, largely contributed to by carelessness or ignorance, but the work otherwise is much more attractive than that in the steel mills, the factories, the railroad yards, in the firing rooms of our ships, or on the farms, or in other occupations too numerous to mention. Generally the men go to work as they please. Most mines are well ventilated and afford comfortable working conditions, the workers suffer from neither the extreme heat of summer nor the cold blasts of winter. It is fortunate for the rest of society that this is true, and that men once engaged in the occupation of mining are loath to take up any other kind of labor; usually there is a surplus rather than a shortage of labor in most of the mining districts of the country.

The general public knows little of the varying quality of coals produced by mines in the same district; of the differing qualities in the various districts and states. For instance, in central Pennsylvania we find some of the lowest volatile smokeless coals of high steaming qualities that exist in the country. There are also veins of coal that are less valuable to the consumer; there are gas coal districts, coking coal districts and, farther west, the higher volatile steam coals, which for steaming purposes are not equal to coals lying on the eastern range of the coal fields.

There are differences in the thickness of the veins, in the character of the roof and in the amount of impurities; great quantities of water to be pumped out at some mines and comparatively little at others; the initial investment necessary in opening some mines differs from that in opening others; consequently, there is great variation in the cost of coal from different mines and in different districts.

The making of a wage scale to suit these varying conditions, and one that is equitable and fair to the miner, is one of the most difficult problems connected with the industry. Nevertheless, through time and experience, the wage scale, as a whole, has grown to balance these unequal conditions fairly well. The mines of the company that I represent, scattered, as they are, through three counties, show varying costs under the same wage scale for labor alone, the variations in cost sometimes running as high as $1 per ton. The miners will hardly believe this, and yet they must see part of the reason for this difference as they come in contact with these conditions daily. Competitive conditions soon bring the price of coal down to where the high-cost and poor-quality mines are put out of business, and a great many miners either have to remain idle for long periods, or remove to other places to seek employment.

### Only Specially Favored Mines Can Run

Today, in the bituminous coal regions, the only union mines that are able to run at all are those that have a superior quality of coal, or that have contracts made earlier in the year, which will soon expire, or railroad-owned mines that operate fairly continuously furnishing railroad fuel. Union mines depending upon industries for the sale of their coal are either being operated intermittently or remaining idle. The startling development within the last few day has been that cargoes

Digitized by Google

of English coal have been offered in the New York and Boston markets at lower prices than coal can be produced for, even in the non-union mines in the Eastern coal regions. Although we hope that this does not indicate permanent competition, it is futile to hope for exports of coal until wages and transportation rates are materially reduced.

The other problems which affect both operator and miner at certain times are matters connected with transportation. Shortage of cars frequently occurs under active business conditions on certain railroads, whereas other railroads fully supply their mines. As a result of these shortages of cars, a system of private car ownership for the steel mills and for public utilities has developed, as well as for some of the large operating companies which supply special trade, and in times of traffic congestion private cars are moved in priority to the rest of the equipment. There is also the assigned car evil, which makes the problems of the small operator, as well as those of the larger operator who depends on railroad equipment for his output, very trying and expensive. This matter, which has been under constant discussion, is in abeyance at the moment because there is a surplus of cars for any mine that can get orders.

### [Relation of Operators to Miners]

We now come to the question that should have an immediate solution; *i.e.*, the present contract and future relationship of operators doing business with the miners' organization. The present contract with the union expires April 1; by or before that date, an adjustment of the present scale to a reasonable basis should be made. Unquestionably, much new construction and new development is postponed until the cost of coal is adjusted and railroad transportation rates revised and substantially reduced. The cost of coal is important to all industries and especially to the railroads, which consume about 28 per cent. of our annual production.

The history of the so-called collective bargaining movement, which originated in the West more than 25 years ago and was carried on through the organization known as the United Mine Workers of America, is too long a story to be told here. It is sufficient to say that the organization has grown through these years; today the United Mine Workers of America command about 60 or 65 per cent. of the labor employed in the soft coal mines of this country; the remaining labor, known as non-union, is engaged by operators who will have nothing to do, through contractual relationship, with the United Mine Workers of America. The collective bargaining theory of making wage scales and arranging working conditions has been developed by the unions into "collective threatening."

It must be admitted that 20 years ago conditions surrounding the bituminous industry of this country were deplorable, both for the miner and the operator, although this country was considered prosperous, compared with other countries at that period; wages in all lines of industry were more or less balanced and the cost of living was somewhat in line with the wages earned. Up to April 1, 1900, the highest wages paid men working by the day was $1.90; motormen were paid $1.75. From 1901 to 1903, the standard rate was $2.25; in 1904, it was $2.40; in 1905, it was reduced to $2.27; in 1907, it was restored to $2.40; in 1910 and 1911, it was $2.53, and it remained at that figure until April 1, 1916, when it was raised to $2.77. The war induced higher wages. The same class of labor was advanced in April, 1917, to $3.60. On Nov. 1, 1917, as a result of another demand on the part of the miners, wages were advanced to $5 a day. The national strike began Nov. 1, 1919 and lasted about six weeks, the men returning to work at a rate of $5.70 per day. On April 1, 1920, under the award of the Bituminous Coal Commission, the wage was advanced to $6. The miners, protesting against that decision, forced another increase on Aug. 15, 1920 to $7.50, so that we see, in 20 years, wages advanced from $1.90 per day to $7.50 per day. The rate for pick mining in the central Pennsylvania district went from 50 cents per ton in 1900 to $1.2803 a ton, the present rate. At these rates, the miners can, and do, earn from $150 to $350 per month. The miners' union takes credit for these advances while, as a matter of fact, they were the result of conditions which affected wages generally up to last year. These increased wages caused increased freight rates, which caused the cost of living to increase, and the vicious circle went on.

### Bituminous Coal Commission Award

The Bituminous Coal Commission appointed by the President to settle the 1919 strike left an award which was to last until April 1, 1922, with a peak of high wages in the mining industry never dreamed of before the war. When, somewhat over a year ago, the collapse in the whole economic structure began, there was violent resistance on the part of all organized labor against reduction of wages, but gradually the inexorable laws of supply and demand forced a readjustment in wages and costs and margins in many lines. The farmer, who had gone along with the tide of prosperity with high prices for wheat and corn, suddenly found that Europe could no longer buy his surplus and pay the high prices, and there was a gradual but sure decline in the prices of his product, so that today the farmer, who is the backbone of this country, is receiving less than pre-war prices for his product and is carrying a burden that is hard to bear. It is estimated that the buying power of the farmer for this year has decreased over eight billion dollars.

The Department of Agriculture has just issued a circular showing the relative fuel value of corn and coal. Already about 1,000,000 bushels of corn have

Digitized by Google

been burned in Western towns because corn is cheaper than coal. Chicago grain men estimate that 25,000,000 bushels will be burned during the winter. What more striking example could be found of the results of one group of workers trying to pass the entire burden of readjustment to others? What more forcible example could be found to prove that the merchant who charges too much for his goods, or the laborer that demands excessive wage rates, simply drives himself out of business and leaves the field to more reasonable competitors?

The trade of the great mail-order houses has been greatly reduced because the farmers could not buy as usual; but while the farmer has had to absorb the shock of this economic change, organized labor has been stubbornly resisting and shutting its eyes to the cold facts, "passing the buck," compelling the farmer, the professional man, and all those with small incomes to carry the burden of the scale of wages.

The two notable forces that are blindly ignoring the economic situation and their duty to the public are union labor on the railroads and union labor represented by the United Mine Workers of America. The president of the United Mine Workers of America reiterates his statement that the present scale shall not be modified, and is supporting demands for a further increase in wages and changes in working conditions that will still further increase costs. The operators, not wishing to be in the position of having repudiated a contract, even if forced to do so through the breaking of a previous one and repeated violations of the present contract by the miners, have continued to live up to their agreement and have seen their trade disappear and many of their employees suffer through lack of work, all because the leaders of the employees are blinded by an exaggerated sense of their power, fighting among themselves for the political control of their organization, squabbling about broken contracts in Kansas and spending millions to raise armies to march through West Virginia and Alabama to extend their tyrannical control to all the coal fields of the United States.

### How Unions Destroyed Good Will

With a continuation of present practices and policies, the disruption of this organization is inevitable, and will come quickly. I consider it a duty for every operator familiar with the conditions to put this situation before the public for discussion, and when it is fully understood I have no fears about the fairness of its decision. Fortunately for this country, there are some miners and some operators who refuse to be led along the road to slavery. In the great coal fields of Irwin, Westmoreland, Connellsville, Latrobe, Johnstown, Greensburg, Black Lick, all of Somerset County, and many spots in Cambria County and other sections of Pennsylvania, together with a large percentage of West Virginia tonnage, miners have accepted an adjustment of their wage scale, are working under non-union conditions, getting fair wages, and are thus enabled to earn a decent living. The failure of the union to recognize changed conditions has destroyed the good will, trade and custom of the operators who have for years recognized the union; these union leaders may be described as the "blind leading the blind."

### The Abominable Check-off

There is an abominable system, called the "check-off," by which practically every man is compelled to belong to the union. We collect from every man the union dues and assessments and pay them over to the officials of the United Mine Workers of America; no other class of employers in the world has ever done such a thing. It is the opinion of government officials that this practice is illegal. The courts will decide, and it is hoped they will soon decide, so that the question will be settled definitely. Just stop for a moment to consider the absurdity of the views of the miners' organization in relation to the check-off. Only recently a Federal Court Judge at Indianapolis, Judge Anderson, rendered a temporary injunction restraining the operators from continuing to collect the check-off from union miners. This injunction was granted on an application of the Borderland Coal Co., representing a group of operators in West Virginia, who claimed that the operators and miners were engaged in a conspiracy and were using the money collected through the system of check-off in an unlawful manner to compel the operators of that district to recognize and deal with the union. Promptly upon the granting of the injunction, many miners went on strike, and it was understood that all of the union miners of the country were to be called out by the miners' organization on the ground that if the operators stopped collecting the dues, it would be a violation of an existing contract. The injunction granted did not change any part of the contract relating to wages or working conditions, but simply prevented the operator from collecting the miners' dues. The absurdity of a strike for this cause seems to me apparent. Nothing in the injunction prevented a miner who wished to pay his dues from paying them to the union officials. If the union leaders and miners planned deliberately to alienate public sympathy, they could not have found a better way than by striking on such an issue. A union that cannot exist by the voluntary payment of its dues by its members has no right to represent the working men of any industry. The shackles which this union has forged, on the miner, the operator and the public must be broken, and when I say this I do not say it with any thought that labor should be denied the right to organize. My contention is against the vicious practices and harmful influences which the policy of the United Mine Workers as now conducted will have upon the future of this nation.

Digitized by Google

Non-union districts that are now operating are making contracts for next year and doing business with an assurance of no strikes, and are working on the basis of the scale paid up to 1919. Operators and miners working outside of contractual relationship with the United Mine Workers have made adjustments in their labor rates and costs which enable them to mine, on an average, 75 cents a ton less than the union operators are operating under today.

### Cost of New Developments

Capital required for the opening and equipment of new mines in our district, with proper housing facilities for employees, will amount to from $4 to $5 per ton of actual annual capacity; in other words, for a mine to produce 300,000 tons annually would require an investment of from $1,200,000 to $1,500,000. This figure does not include a cent for the value of the coal land, which varies greatly on account of difference in quality, accessibility, etc. Who would invest a dollar in such an enterprise under domination of the union as at present controlled? New development has stopped except by non-union operators.

As a result of the conditions under which we have been operating, our customers have grown to know that our performance is uncertain. We have to put in our contract a clause providing for immunity in case of strikes. Strikes are so frequent that we dare not take the risk of obligating ourselves to fill a contract because of the loss that might ensue. The result is that the consumers of coal in the markets to which we have access have been diverting their business to non-union operators and non-union districts. Many consumers have sympathy for the position in which we find ourselves. They tell us very plainly that they cannot renew relations with us until we get not only our costs and prices adjusted to a fairly competitive basis, but that we must give a better assurance, no matter what the price may be, that they will get the coal when they want it.

I have seen wise leaders of labor organizations in my time, but never have I seen such harmful leadership of organized labor as we have to deal with today in the United Mine Workers of America. I am not mincing the facts. It may be that a strike will ensue; in all probability it will. We should be left to fight it out, because the fight we are making and the arguments I am making today are principally in the interest of the general public, as well as in the interests of the operators and the miners. It is well for people to "put their houses in order" because the conflict is bound to come; in my judgment, there is no avoiding it. It is to be hoped that there will be no government interference or compromises and that when it is settled, the leaders of our industry—not the small-minded men, but the men of experience, the big broad-minded men, men who have sympathy—will be willing to sit down and make a scale with a rate of wages that is fair and decent and comparable with the rates paid in other districts. We do not believe that the miners should be pauperized. They are an essential part of the working force, necessary to keep our present day civilization going, and they must not be treated as slaves. I would be one of the first to resist going below what is fair and just. The 1919 scale of wages, which gives a man $5 a day, is fair compared with the present cost of living. It should not be more; in my judgment, it should not be less. Any compromise above that figure would only postpone the day when normal business conditions will again prevail.

I have just read President Harding's address to Congress, in which he treats the union labor problem and its relation to the public welfare in part as follows:

> The right of labor to organize is just as fundamental and necessary as is the right of capital to organize. The right of labor to negotiate, to deal with and solve its particular problems in an organized way, through its chosen agents, is just as essential as is the right of capital to organize.
>
> Just as it is not desirable that a corporation shall be allowed to impose undue exactions upon the public, so it is not desirable that a labor organization shall be permitted to exact unfair terms of employment or subject the public to actual distresses in order to enforce its terms. Just as we are earnestly seeking for procedures whereby to adjust and settle political differences between nations without resort to war, so we may look about for means to settle the differences between organized capital and organized labor without resort to those forms of warfare which we recognize under the names of strikes, lock-outs, boycotts and the like.

It seems to me these principles are fundamental and that this is the psychological moment for giving them serious consideration with a view to securing legislation based on them, in order that the liberty guaranteed by our Constitution shall be preserved for the people of this nation as a whole.

### Miners' Wages and Railroad Rates

A proper adjustment of miners' wages will help the railroads to lower their rates, and railroad rates must be reduced. We are paying twice as much for the hauling of a ton of coal from our fields today as we did in 1915; the rate to tidewater was then $1.55; it is now $3.11. Every manufacturer throughout the East who is endeavoring to lower his cost is clamoring for lower freight rates. His customers are demanding lower costs. The professional man, the salaried man and people with small incomes have long been subjected to extortionate prices resulting from war conditions. This group will not tolerate having the operators enter into any combination or any agreement which tends to keep the price of coal on a war basis. With $5 a day for day men, and with miners able to average $7.50, they will be earning nearly double what they earned up to April 1, 1915, and this will be nearly double the rate paid for common labor in the steel mills of the country.

# Medal Awarded to Charles Warren Goodale for Safety and Welfare Work

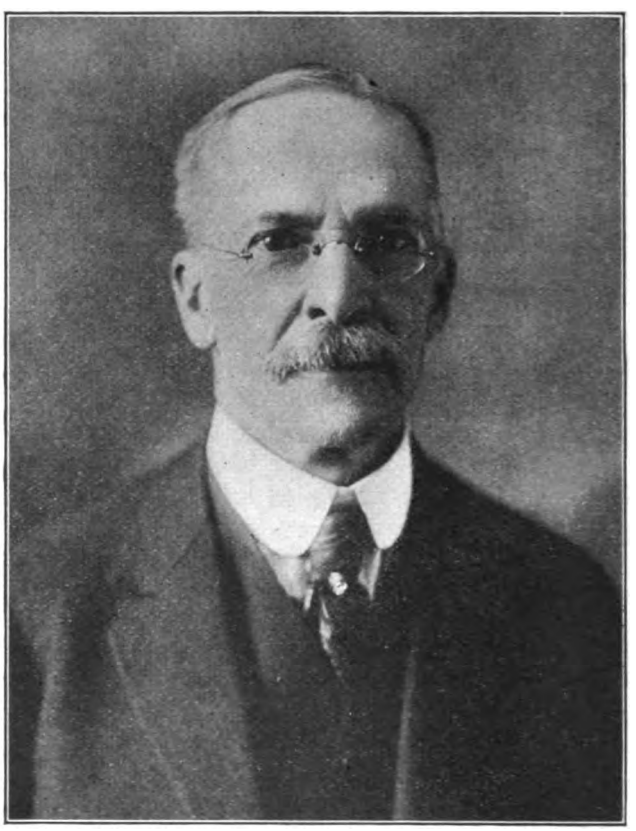
THE gold medal of the Mining and Metallurgical Society of America was presented, on Jan. 10, 1922, to Charles Warren Goodale, "for signal services in furthering the welfare and safety of workers in the mining and metallurgical industries of America." The presentation was made by Dr. J. E. Spurr, president of the Society for the year 1921, at the annual meeting held in New York City.

Dr. Van H. Manning, formerly director of the U. S. Bureau of Mines, made the first address. Toward the close of his brief speech, he said, "It has happily been suggested, 'Let us balance our praise of war heroes by pausing to honor a hero of peace.' We have with us tonight a man who has been a leader and inspirer of thousands of his contemporaries. . . . His zeal in the great work of increasing the safety of men engaged in mining and metallurgical operations has become an obsession with him. . . . That he has been successful is evidenced by the great work, of which I have personal and intimate knowledge, done by him in connection with the Anaconda Copper Mining Co. and its subsidiaries."

Dr. J. F. Kemp gave a brief sketch of Mr. Goodale's career, in the course of which he said, in speaking of the consolidation of the Boston and Montana, the Anaconda, and smaller companies, "at the same time electric current was introduced for haulage in the mines and on the surface for the running of air compressors and the hoisting of the cage. . . . We can see that there was great danger to the miner and that safety first became a very important feature of the work. . . .

"As time has passed, we find all the southeastern peoples of Europe, many of them unable to speak English, employed in the mines. It becomes a very difficult problem to maintain proper precautions for safety with so diverse a series of people and with such careless men. In later years, all these various lines of safety first have fallen to Mr. Goodale and very successfully and admirably has he carried out the heavy responsibility of his position. Within the last year, with all the large mines practically idle and only the smaller silver mines in operation, with fifteen or twenty thousand men thrown out of work, with families necessarily in need, the welfare work has become an operation of the very first magnitude. . . . The Society has never taken a more admirable step than when it decided to confer its medal upon Charles W. Goodale, the best loved man in Butte."

Mr. Goodale was a member of the class of 1875 of the Massachusetts Institute of Technology. He began his professional work in 1876, with the Boston & Colorado Smelting Co. In 1880, he became superintendent and manager of the Boston & Arizona Smelting & Reduction Co. at Tombstone; and five years later went to Butte to be superintendent of the Colorado Smelting & Mining Co. In 1898, he became affiliated with the Boston & Montana Consolidated Copper & Silver Mining Co.,



CHARLES WARREN GOODALE.

as superintendent of the smelter at Great Falls; three years later he became assistant manager, and in 1912, was made manager.

Since the Boston & Montana was merged with the Anaconda Copper Mining Co., Mr. Goodale has been chairman of the Bureau of Safety of the company. He will present at the New York meeting of the Institute, Feb. 20–23, a paper by himself and Mr. Boardman (see page 38) which outlines the work of the Bureau of Safety, but tells only by implication of his own share in the tremendous task.

# American Engineering Council's First Annual Meeting

By EDWIN LUDLOW

President of American Institute of Mining and Metallurgical Engineers

ROUNDING out a year of improved organization, substantial accomplishment and strengthened purpose, the American Engineering Council of the Federated American Engineering Societies held its first annual meeting at the Cosmos Club, Washington, Jan. 5 and 6, Dean Mortimer E. Cooley of the University of Michigan, president of the Council, presiding. Officers were chosen, the work of the past year was reviewed and discussed, action was taken on important matters of public and technical service, new financial arrangements were put into effect, committees were named, new policies were sanctioned and old ones reshaped, and a broad and definite program was outlined for the next twelve months.

A leading event of the meeting was a dinner in honor of Herbert Hoover, who, addressing the members of the Council and their guests at the University Club, praised the work of the Committee on Elimination of Waste in Industry as a great and lasting public service, pointed the way for new engineering effort in the public interest, and expressed renewed devotion to the ideals of the Council. Resolutions of appreciation of the service of the Secretary of Commerce were presented to Mr. Hoover.

## Long Discussion on Licensing

The council engaged in a long discussion of the question: Does the American Engineering Council approve or disapprove of the principle of licensing or registering engineers? Prof. Donald Derickson of Louisiana was a leader of the affirmative side, asserting that the experience of his state had been such as to justify the conclusion that the licensing statute had been beneficial alike to the public and the engineer. Gano Dunn, of New York, in a spirited speech opposed action by the Council at this time, saying that the whole question should be carefully studied before a definite policy was adopted. Maj. F. J. Miller of New York, and Dean Perley F. Walker of the University of Kansas supported this view. Philip N. Moore, of St. Louis, speaking for the mining engineers, stated that as a group they were opposed to licensing and asked that this matter be not again referred to a committee but that Council put itself on record as opposed or in favor of licensing. Gardner Williams, of Detroit, then made a strong plea for licensing and begged that the question should not come to a final vote, as it would appear that any action would be by only a small majority. It was then voted to lay this question on the table.

At the meeting of the Executive Committee following the Council meeting, Dean Cooley appointed a committee of three to examine further into the subject and report. This committee consists of Gardner Williams of Detroit, P. N. Moore of St. Louis, and A. S. Dwight of New York, as chairman.

## Encouraging Reports on Outlook

Dean Cooley, in opening the sessions, declared his confidence in the future of the Council and outlined generally his plans for more effective organization to be carried out in coöperation with the executive secretary, L. W. Wallace. President Cooley will soon start on a tour of the South and Southwest, to further the work of organization.

Encouraging reports of the outlook for accretions to membership were reported to the Council. The secretary's report showed that on Jan. 1, 1921, the membership of the society was composed of 6 national and 14 state and local societies, a total of 20. On Dec. 31, 1921, there were 8 national and 20 state and local societies, a gain of 8 member societies representing 1414 member engineers.

Conditions in the mining industry, as stated by Edwin T. Ludlow, president of the American Institute of Mining and Metallurgical Engineers, and Col. Arthur S. Dwight, were responsible for a reduced contribution by the Institute to the Council for the coming year. As a consequence, the assessments levied upon the other member societies were cut down proportionately. This was accomplished by constitutional amendment. Both Mr. Ludlow and Colonel Dwight assured the Council that the Institute was warmly in sympathy with the Federated, with which it was anxious to go forward. Sharp reductions in the budget were thus made necessary, and, though the Council begins the year with a scarcity of funds, assurances were given that if the Mining Engineers can, either by increased appropriation or by personal subscription of its members make up its pro rata share of the full assessment, then the other societies will also contribute their full proportion and enable American Engineering Council to continue its work.

Digitized by Google

The balloting for officers resulted in the re-election as vice-presidents of Dexter S. Kimball, Dean of the College of Engineering, Cornell University, and J. Parke Channing of New York. W. W. Varney of New York was again chosen treasurer. L. W. Wallace was re-elected executive secretary by unanimous action of the Executive Board.

The Council voted to coöperate in the movement to prepare for cyclical industrial depressions and unemployment by resort to public works projects. On this subject, the Council received a proposal from Mr. Hoover, and it was decided to open conferences with him to ascertain in what way the Council could best provide effective aid.

Considerable discussion was provoked by the plan to establish a Federated journal which would be sent to every engineer represented by the Federated. The Publicity Committee made no recommendations and the Council took no definite action. It was generally agreed that some such contact should be established between the Federated and its enrolled membership, but there was sharp diversity of opinion as to its form.

New representatives on the Council were announced as follows: American Society of Mechanical Engineers: Francis Blossom, Charles A. Booth, Gano Dunn, H. H. Esselstyn, W. S. Lee, I. E. Moultrop, John H. Stevens, A. E. Walden; Society of Industrial Engineers: Prof. Joseph W. Roe; American Institute of Mining and Metallurgical Engineers: C. H. MacDowell (succeeding J. W. Richards); Louisiana Engineering Society: Prof. Donald Derickson; Iowa Engineering Society: Lloyd B. Canfield; Duluth Engineers Club: W. H. Hoyt; Milwaukee Engineering Society: Albert Blatz, Jr.

The Executive Board of the Council for 1922 is made up as follows: H. E. Howe, Washington, American Institute of Chemical Engineers; Prof. C. F. Scott of Yale, L. B. Stilwell and Calvert Townley of New York, J. H. Finney of Washington, William McClellan of Philadelphia, and L. F. Morehouse of New York, representing the American Institute of Electrical Engineers; J. Parke Channing and A. S. Dwight of New York, Charles H. MacDowell of Chicago and Philip N. Moore of St. Louis, the American Institute of Mining and Metallurgical Engineers; L. P. Alford of New York, E. S. Carman of Cleveland, Dean D. S. Kimball of Cornell, Prof. A. M. Greene of Troy, Dean Perley F. Walker of Kansas, W. S. Lee of New York, Dean M. E. Cooley of Michigan, American Society of Mechanical Engineers; Prof. Joseph W. Roe of New York, Society of Industrial Engineers; Morris L. Cooke, Philadelphia, Taylor Society; W. E. Rolfe, Associated Engineering Societies of St. Louis, W. W. Varney, Baltimore.

Regional Directors chosen for 1922 are: District No. 1 W. B. Powell, St. Louis; District No. 2, Gardner S. Williams, Ann Arbor, Mich.; District No. 4, W. J. Fisher, York, Pa.; District No. 5, Paul Wright, Birmingham, Ala.; District No. 6, Lloyd B. Smith, Topeka, Kans.; District No. 7, O. H. Koch, Dallas, Tex.

The request of Dr. B. Stepanek, the Czecho-Croat Minister to the United States, that his government be given copyright privileges on "Waste in Industry" has been approved by the Committee on Procedure. The translation has been made and the waste report will be widely circulated in that republic. Increasing interest in the waste report was reported. The first edition of 2000 copies has been exhausted and preparations are being made for the second edition. Inquiries concerning the work of the Council's Committee on the Elimination of Waste in Industry are coming in from all over the world and numerous engineering, civic and economic organizations have held meetings to discuss its findings.

The work of the committee on employment, which was mapping plans for a paid employment service, has been delayed owing to the illness of the chairman, Morris L. Cooke of Philadelphia.

---

## Zirconium, the Mystery Metal

ON ACCOUNT of various properties and uses that have been attributed to it, zirconium has at times been styled "the mystery metal." Its compounds have numerous important uses and more uses will doubtless be found. Investigations in recent years have indicated that sintered or coherent zirconium metal is resistive to acids and that it can be used for electrodes. The salts have been used in the textile industry as mordants and also for weighting silk.

Zirkite firebrick is used for furnace lining as well as for other purposes where a refractory having a low coefficient of expansion, high melting point, and maximum resistance to slag corrosion is demanded. Although zirconium oxide has not proved satisfactory for gas mantles nor for arc lamps, it has been used for polishing powders, insulators for both heat and electricity, and with fair success in the Nernst lamp. Being absolutely non-poisonous, zirconium oxide is finding a use in paints and lacquers, where its resistivity to physical and chemical agents is proving highly valuable. As an abrasive, zirconia, zirconium silicide, and zirconium carbide are suggested for a variety of uses, the carbide particularly as a substitute for the diamond in cutting glass. Zirconium oxide, because of its non-toxic nature, is used in place of bismuth nitrate or carbonate in Rœntgen-therapy. Crucibles prepared from zirconium oxide have proved superior for high-temperature work to any crucibles procured on the market.

The results of the investigations of the Bureau of Mines are available in Bulletin 186, "Investigations of zirconium with especial reference to the metal and oxide," by J. W. Marden and M. N. Rich, which is distributed by the Superintendent of Documents, Washington, D. C., at a price of 25 cents.

# Block-signal and Dispatching Systems in Metal Mines*

By R. T. MURRILL

Safety Engineer, Inspiration Consolidated Copper Co., Inspiration, Ariz.

BLOCK-SIGNAL and dispatching systems have been in use on surface railways for years, but only recently have they been applied to underground mining conditions. Formerly, all ore was moved underground by hand tramming; the surface openings were numerous and fairly close to the ore being mined. As the tramming distances increased, animals were brought into service. Then came the locomotive, and since its introduction, haulage lines have gradually been reduced to fewer levels and to fewer surface openings until more than 20,000 tons are being handled daily on one level in some of the larger mines. Under these conditions many trains must use the same tracks, and signal systems have become necessary.

In some cases it has been found more advantageous to use train dispatchers than to install signal devices. The dispatcher may be simply a flagman at a busy point or he may have mechanical signals to operate at more distant points. At the Inspiration mine, Inspiration, Ariz., the station is equipped with a switch-control board, whereby the dispatcher throws electrically all track switches in a certain block, which gives him complete control over all trains passing through that

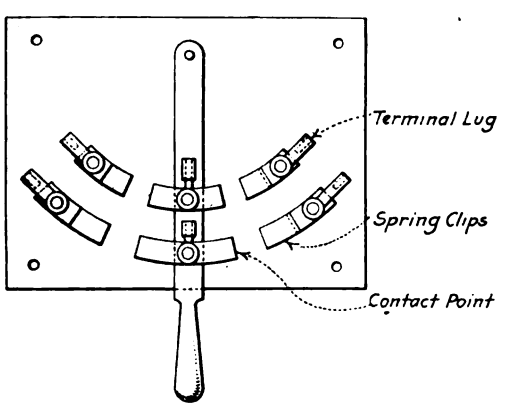

FIG. 1.—TYPICAL SWITCH FOR MANUAL OPERATION.

block. In a few cases, dispatcher stations are established in connection with a signal system.

Signal systems vary from many simple forms to the highly complicated electrically operated block-signal systems. The simplest form is used at shaft stations or at points where a main line branches, a short distance from the shaft station, where loaded trains are brought in on the various branches. However, the usual problem is a long main line with branches coming in at various places, but where the presence of trains in limited portions only need be indicated at one time. A series of blocks is therefore laid out, and at the end of each block, or wherever branches enter a block, a signal shows whether or not a train is in that section of the track. Block signals vary greatly in arrangement and apparatus employed but divide themselves into two general classes, manual and automatic.

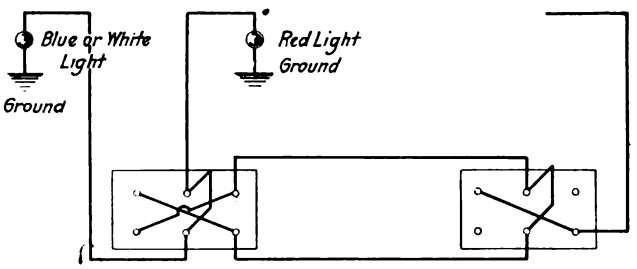

FIG. 2.—WIRING DIAGRAM FOR A SIMPLE MANUAL BLOCK.

## MANUAL BLOCK SIGNALS

In the manual block system, the signals are operated or controlled by hand. The simplest form is obtained by running an extra electric circuit alongside the tracks, and connecting to this red lights placed at the ends of the blocks, at curves, branch lines, etc. Whenever a train enters a block, the driver or trainman throws an electric switch nearby, lighting the red lamps along the block. When a train leaves the block, the switch at that point is thrown, cutting out the red and turning on the white lights. Many forms of switches are in use. The most common, and one of the most practical, is that of the type shown in Fig. 1; the latest designs are housed so that connections and contacts are not exposed. The switch is generally placed on a post beside the track where the driver can reach it without leaving his seat. A wiring diagram for a simple manual block using this switch is shown in Fig. 2.

## AUTOMATIC BLOCK SIGNALS

In the general acceptance of the term, an automatic block system is one in which each block is operated by power, usually electric, and is controlled by one or more track circuits, so that it is automatically set at stop when a train enters the block and remains so until the block is clear. The entrance of a train into a block, at

*Read at Tenth Annual Congress, National Safety Council, Boston, Sept. 26 to 30, 1921. To be presented at February Meeting A. I. M. E. for discussion.

Digitized by Google

either end or at an intermediate point, the presence of a car in the block or inside certain limits of the turnouts, or the setting of the track switch for a turnout, will cause the display of a stop signal, which will be displayed until the switch is in proper position and every part of the track included in the circuit is clear and safe for passage.

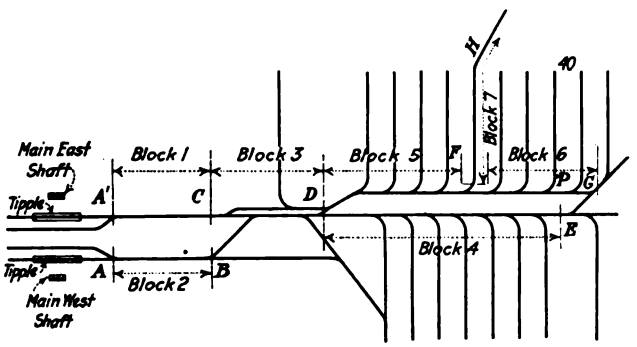

FIG. 3.—PARTIAL PLAN OF 600-LEVEL SHOWING GENERAL LOCATION OF BLOCKS.

All underground automatic systems are so arranged that when necessary the signals may be passed when in the stop position. A train may proceed, when it is deemed advisable, by sending a flagman a certain distance ahead. The trains usually travel at a speed that makes it possible to stop quickly.

Signal lights are generally operated through track circuits carrying low-tension currents, on account of imperfect insulation. At each rail joint, wire bonds secure electrical continuity and insulating joints are placed in the track at the end of each block section. Control by track circuits is the only system today considered by experts to be fundamentally safe, as it gives each train the means of maintaining at all times its own protection.

## THE INSPIRATION SYSTEM

At the Inspiration mine of the Inspiration Consolidated Copper Co., an automatic block-signal and dispatcher system is in operation on the 600-ft. level. This system is an adaptation of the standard equipment used for high-speed surface railway traffic, the equipment being furnished by the General Railway Signal Co., Rochester, N. Y.

The trains consist of 5-ton ore cars drawn by compressed-air locomotives, which have a maximum speed of 10 to 12 mi. per hr. but which are limited to 8 mi. per hr. on tangents and to 5 mi. per hr. on curves or when passing over switches that face an approaching train. The average mine haul is 0.475 mi. About 217 round trips per day are made to the tipples at the main shafts and about 30 trips on the level with waste and supplies, giving a total of 247 train trips per day. About 232 of these round trips, or 464 single trips, pass one point *D*, Fig. 3, but 496 trips have passed it in one day. To handle this traffic properly, the automatic signal system was installed with a dispatcher station at the busy point.

The level is divided into a number of blocks and signal lights have been placed at the ends of each block and at other prominent points on the main lines, also on the curves of all turnouts from the main lines, as shown at point *P*. These lights are operated automatically, by the passing of a train or the throwing of a track switch level. A red light signifies danger and a blue light, safety; a green light indicates that the track is clear on the siding or turnout to which the switch bearing it leads.

The lamps on the main line always show blue when the tracks are clear. The lamps on the curves *P* of the turnouts of the loading drifts show red until the track switch to the main line is thrown, when they show blue if the main line is clear. Red lights always show when trains or cars are on the tracks, when track switches are open or split, and when electrical connections are broken. Trains are permitted to pass red lights only after an investigation as to the cause and then only if preceded by a flagman. No light has the same significance as a red light and trainmen must stop until passage is proved to be safe; then the train must proceed as when a danger signal is displayed.

Each of the signals consists of two 110-volt, 10-watt, 2-candlepower lamps in multiple. These lamps are mounted in porcelain receptacles in small cast-iron boxes. The boxes are equipped with 4½-in. diameter lenses and with guides that slip over brackets attached to caps or posts of drift sets.

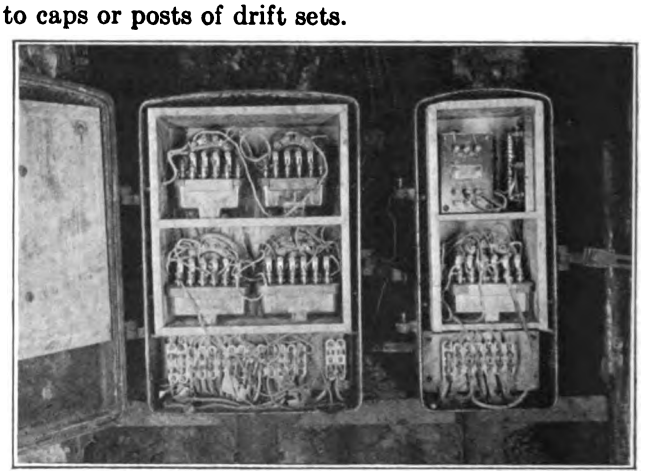

FIG. 4.—TRACK RELAYS AND TRANSFORMER.

The track circuit is the heart of the system, as it furnishes the power necessary for operating the signals; 25-cycle alternating current is used for this purpose. The line current as received from the mine substation is 110-volt; track transformers in each block operate upon 110-volt primary and give almost any voltage up to 14 volts on the secondary. Rails, under the best conditions, make very inefficient transmission lines; so relays are used. The relay controls, through its contact points, another circuit supplying the power to operate the signals. The relays and track transformers are housed in cast-iron boxes, as shown in Fig. 4. A diagram of the track wiring for a single turnout is shown in Fig. 5.

Digitized by Google

An important feature of the installation is the track switch-circuit controller, which causes the proper signals to assume the danger position when a switch is open or split. These controllers are attached by adjustable rods to all switch points and contacts are arranged to make or break when the switch points are moved ¼

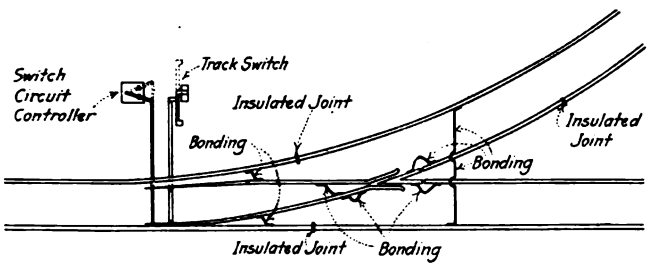

FIG. 5.—TYPICAL TRACK WIRING AT A TURNOUT FOR AUTOMATIC BLOCK.

in. from the closed position. One switch box, shown in Fig. 6, is placed at each switch.

At the dispatching station *D*, Fig. 3, the key point of the haulage system, there is a switch-interlocking machine, Fig. 7, equipped with sixteen levers, each of which controls the mechanism for operating a track switch. This mechanism consists of a series-wound direct-current motor connected through a shafting and friction clutch to a gear arrangement for throwing the switch. The mechanical operation of the track switch also operates the signals of the block-signal system. In addition, the dispatcher has independent means of signaling the trains when he wishes them to proceed or stop.

FIG. 6.—TRACK SWITCH-CIRCUIT CONTROLLER.

Indication is given on the board, when a track switch is not thrown completely and locked in position; and there is an arrangement whereby a switch cannot be moved under a passing train. In case of a wreck or other emergency the switch may be thrown by unlocking the control lever. A 1 by 1½-in. piece of glass, bearing the switch number, is placed above each lever; when a train is within a certain distance of the switch, a small electric lamp behind this glass is lighted. The dispatcher has direct telephone connection with the tipple station and with switch *B*, which cannot be seen

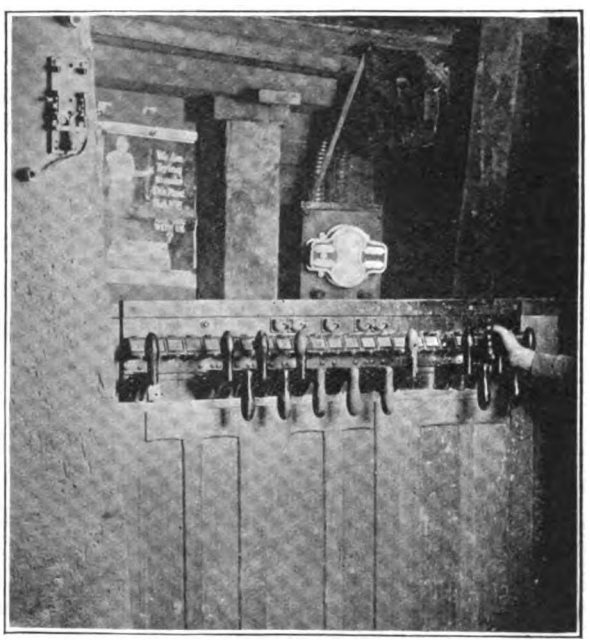

FIG. 7.—INTERLOCKING BOARD.

from his station. The switch-throwing mechanism is shown in Fig. 8.

To show the operation of the system, suppose that a train is to be taken from a loading drift, No. 40, to one of the tipples at the main shafts. As the train approaches the entrance to the main line, a flagman runs ahead and, if the main line appears to be clear in that block, throws the switch; if the red light at *P* changes to blue, the train proceeds. If the red light continues to show, it indicates that block 6 is not clear and the train must wait behind the signal *P* until the block is cleared. Before the train can continue into block 5, a blue light must show at point *F*, and before it goes to block 3 a signal must be received from the dispatcher at *D* in addition to the block signal at that point. The dispatcher determines to which tipple the train will be sent and gives it the right of way by throwing the proper switches.

A train going back follows a similar procedure. For instance, a train leaving the main west tipple must have a clear signal at *A* before it can leave the tipple station. At *B*, it must await a signal from the dispatcher before it rounds the curve into block 3. The dispatcher must throw the switch at *B*, from his board, which also changes the block signal at *B* to safety, before giving the signal to proceed. The dispatcher then sends the train into block 4 or 5, as he desires.

Block 7, Fig. 3, of the system is wired to give what railways call an "absolute permissive block." By this

Digitized by Google

is meant that following trains are permitted to enter an occupied block but they must be prepared to stop on a flagging signal, while opposing trains are given an absolute indication to stop. This block is on a turnout leading to several loading drifts. At the entrance *F* to the block three signal lamps are placed in a row but only three indications are given by the lamps. The red light alone indicates danger and the blue light indicates that the track is clear. The red and green together indicate that the track is occupied and that a following train may enter but must be prepared to stop at any time. This permits a number of trains to follow one another into the block and thereby increase the capacity of that section of track.

### Requisites of Block-signal Systems

All block-signal systems must meet a few fundamental requirements. In the first place a system must be simple and easily understood by the train crew. Mine-haulage conditions differ much from the surface-haulage lines. A railway locomotive driver reaches

Fig. 8.—Switch-throwing mechanism.

his position only after many years of service and that often on the same road; in a mine, the train crews change more frequently and men from almost any position may soon learn how to operate a mine motor. Besides, a train in a mine usually goes backwards as much as forwards, so the rear flagman also must watch the signals. The rear flagman may or may not have worked on trains before, as it is sometimes necessary to use men from other parts of the mine as flagmen. The signal system must therefore be one that the trainmen can comprehend quickly. Indications that trains are in neighboring blocks are usually confusing and often unnecessary; it is best to have each block complete in itself, if possible.

There must be a positive signal for proceeding, not the mere absence of a signal. Then, if a light goes out, a danger signal will not be accidentally changed to a clear signal. The absence of a signal should have the same effect as a danger indication. Blue or green lights should be used as signals for proceeding, rather than white lights. The breaking of a red lens will not then change a signal from stop to proceed or a neighboring white light will not be mistaken for a signal light. In manual block systems it has been common practice to use only red and white lights, but this practice should be discouraged.

The choice of a block-signal system for any particular mine depends largely on the volume of traffic to be handled on the levels. Mines having many haulage levels have usually only a few trains to a level and find manual operation of the blocks adequate. Layouts of many levels can be arranged with run-arounds and with one-way traffic on certain lines, so that manual systems are permissible. Mines having a congested mining area and handling large tonnages of ore and waste, however, find the automatic systems a necessity.

There are many forms of block signals between the simple block system described and the Inspiration automatic system. An interesting one is used with trolley locomotives at the Arizona Copper Co. A wire, strung parallel to the trolley wire, was connected to lamps at each end of a block and grounded. Current was furnished to the lamps by the pantagraph collector bridging the trolley wire and the signal wire. The indication of a locomotive in the block is positive, but the presence of cars without a locomotive is not indicated. Its principal feature is the low installation cost.

### Advantages of Different Systems

Each signal system has its particular advantages. The manual method has the advantage of low cost of installation and maintenance, and its blocks can quickly and easily be changed or extended. The automatic (track-circuit) method has the especial advantage of eliminating the human factor in signaling, as far as possible. The use of track-circuit control of the signals makes the train at all times active in maintaining its own control. J. P. Coleman, in the Third Annual Report of the Block Signal and Train Control Board of the Interstate Commerce Commission, says:

> Perhaps no single invention in the history of the development of railway transportation has contributed more toward safety and dispatch in that field than the track circuit. By this invention, simple in itself, the foundation was obtained for the development of practically every one of the intricate systems of railway block signaling in use today wherein the train is, under all conditions, continuously active in maintaining its own protection. In other words, the track circuit is today the only medium recognized as fundamentally safe by experts in railway signaling whereby a train or any part thereof may retain continuous and direct control of a block signal while occupying any portion of the track guarded by the signal.

Both direct and alternating currents are used for track circuits but the alternating-current system gives more economical operation and maintenance. An alternating-current track circuit is obligatory in mines using trolley locomotives in order to prevent the track relays from operating on the traction current or stray currents.

The development of railway signaling in general has called for much study and a large money outlay. The block-signal system was introduced primarily for safety, but where trains are frequent it has become an element of economy.

# Fire Prevention and Fighting in Metal Mines*

By H. M. WOLFLIN
Superintendent of Safety, Industrial Accident Commission of California

SOMEWHAT more than a year ago the writer collected some extensive notes on metal-mine fires and a paper on metal-mine fire prevention and fighting, a summary of these notes, was hastily prepared, with the assistance of G. Chester Brown, chief mining engineer, Industrial Accident Commission for the National Safety Council meeting. This summary, which is admittedly incomplete, is submitted in the hope that it will evoke some discussion that may result in a reduction in metal-mine fire hazards, somewhere along the line. To accomplish such a reduction does not require the application of complicated scientific data. The use of just a little care, a small amount of thoughtfulness and a bit of common sense will work wonders.

## Underground Fire Fighting

There may be some interest in a short list of conclusions of a rather general nature that were reached in connection with some recent mine-fire fighting operations. No effort has been made to cover the field; the items have been jotted down loosely, and very hastily, in the order in which they occurred to the writer. Originality is claimed for only a few of them.

1. Temperature readings and analyses of mine-air samples, systematically taken, are invaluable aids to effective metal-mine fire fighting and recovery operations. The analysis of the return-air samples frequently gives a surprisingly accurate indication of conditions existing underground.

2. Employees must be thoroughly trained in the use of mine rescue apparatus, because a relatively slight difference in the amount of training makes a vast difference in the amount of work they can perform under oxygen. In general, slender, wiry men make better apparatus men than those of heavy, more muscular physique, although there are frequent exceptions to any such general statement.

3. Surprisingly high temperatures, up to 165° F. or 170° F. can be endured for short periods by wearers of mine rescue apparatus if the air is dry, but lower temperatures, 135° to 140° F. are almost unbearable if the air is very moist.

4. There is likely to be an urgent need of mine rescue equipment and thoroughly trained men familiar with the mine workings at every timbered metal mine.

5. The choice of fresh-air bases, when performing mine rescue work, is very important, for it must be certain that the air is not contaminated by gases from the fire. If natural ventilation is depended upon, the air current must be watched with care to see that it does not reverse.

6. The strictest discipline is necessary to prevent men who are returning from the fire zone from removing their apparatus before they reach the fresh air base.

7. Mechanical ventilation greatly simplifies metal-mine fire fighting operations and increases the safety of the men engaged in the work.

8. The products of combustion from a fire diffuse with great facility through closely filled ground for distances that are surprising. This is true even when differences in atmospheric pressure are relatively slight between the burning workings and those that are not affected by flames. Bulkheads in filled ground are absolutely useless, therefore, for fire-fighting purposes, as a general rule.

9. It is advisable to have bulkheads continuously and frequently patrolled even though they have been recently completed and carefully inspected.

10. If moist clay can be secured in sacks (or dry clay sacked and moistened) one of the quickest methods of building a satisfactory bulkhead in a drift or cross cut is to put up a wall or brattice of 2 by 12-in. or 2 by 6-in. boards nailed to posts or stulls and fitted as closely as possible at the ends, then to nail two or more 3 by 3, or 4 by 4-in. strips on the outside and add another board wall, fastened to the strips, moist clay being tamped between the walls as the outside wall is put up. The outside wall should be calked carefully with clay, especially around the edge and at the top and bottom.

11. When bulkheading timber drifts or cross cuts, a tight seal rarely, if ever, can be made unless all lagging is cut and a section removed, and all loose rock and dirt taken down before the bulkhead is started.

12. Close observation of both candle and canary birds is necessary if men working without mine rescue apparatus in the fire zone are to be spared the nausea and excruciating headache of slight CO poisoning. If men working hard are using a bird to warn them of carbon monoxide, the bird should be kept moving enough to make it pant, otherwise men may be affected before the bird shows distress.

13. The resistance of individuals to low percentages of CO varies between relatively wide limits. Fre-

*Presented at the Mining Section of the National Safety Council, Boston Meeting, Sept. 27-30, 1921.

Digitized by Google

quently more robust individuals with large lung capacities are the first to succumb.

14. Timber fires burn and spread more rapidly than coal fires and conversely die down and cool off more rapidly when the air supply is checked. They are extremely deceptive and likely to blaze up when it is thought that they have been extinguished.

15. When the fresh-air supply is restricted, an underground fire tends to travel against the air current, even though the current may be coming from below; if the air is moving at higher velocities, so that the supply is more plentiful, the fire may travel both ways. If the draft is extremely strong, the fire will probably travel with it.

16. Reliable means of signalling from skip or cage should be maintained at all times during fire-fighting operations in shaft mines. The method of signalling becomes extremely important when it is necessary to ride skip or cage in irrespirable atmospheres.

17. The presence of carbon monoxide in the mine air indicates an active fire (except for the relatively small amounts of CO generated in blasting operations), but the absence of carbon monoxide is not a positive indication that the fire has been extinguished.

18. Finally, it is pointed out that effective organization of fire-fighting forces is of paramount importance. Men, equipment and supplies mean nothing, can accomplish nothing, without thorough organization and the strictest discipline. This is regraded as the most important of all the suggestions and observations.

### Prevention and Protection

In connection with the broad problem of metal-mine fire prevention and protection, the following somewhat general observations and suggestions may be of passing interest:

1. All wooden headframes, wooden structures and supplies of inflammable materials near any mine entrance should be removed or replaced by fireproof structures. If this can not be done, at least such wooden structures should be made as nearly fireproof as possible by means of gunite or some other equally efficient method. All planked floors around the collar of the shaft or at the portal should be removed and non-inflammable construction substituted.

2. Mine timbers should not be piled in the immediate vicinity of the collar of the shaft or at the portal of an adit or a tunnel.

3. Proper storage of dynamite in fireproof places is essential. Boxes of dynamite should not be left near the collar of the shaft or at the portal of an adit or tunnel.

4. Removal of all accumulation of inflammable waste material and refuse from the mine or near the vicinity of the collar of the shaft is important.

5. Proper storage of gasoline or oil at an adequate distance from the mine entrance should receive attention.

6. If underground pump stations or hoist stations need support, steel and concrete or at least gunited timber should be used.

7. All oily waste should be removed promptly from the vicinity of pump or hoist stations and pending removal should be kept in metal receptacles carefully placed and protected.

8. Electrical apparatus, especially wiring and transformers, should be properly installed and carefully protected. All electrical equipment should be placed in fireproof stations.

9. The installing of adequate underground and surface fire-fighting equipment, and the organization of fire-fighting crews are worthy of the most active attention.

10. Fire drills on the surface and underground should be conducted frequently and thoroughly. Those commonly conducted underground are pitifully inadequate and generally come at such long intervals and involve so few men that they are almost worthless. How many men in the average metal mines have an adequate knowledge of the location of escapeways and fire-fighting equipment? How many receive intelligible instruction in these important items with sufficient frequency to retain it with any degree of accuracy?

11. "Second exits" or escapeways are generally intake airways. The best chance that men have when trapped in this way is to bulkhead themselves in dead-ends and wait for rescue. Frequently splitting the air in the ventilating current reduces this danger.

12. Every deep metal mine should be equipped with an efficient means of mechanical ventilation by which the air currents can be reversed quickly, if necessary; and every such mine in which several levels are being worked simultaneously should have its air circulation divided into a number of splits.

13. Some provision should be made to give danger signals or "all out" signals to underground men. Every metal mine should be equipped to introduce a stench into the compressed air lines in cases of emergency, and a supply of the stench-making material should be on hand at all times. Such arrangements are easily made and are not expensive, yet may be the means of saving many lives especially if all men are well drilled in their use.

14. Crews should be organized for effective between-shift inspections of timbered workings, shaft stations, airways, pump stations, etc.

15. Proper fire doors should be installed at strategic points to assist in the control of the ventilation.

16. The introduction of miners' electric cap lamps, and forbidding men to carry matches, flame-making devices, or smoking materials would be an important item in the reduction of underground fire hazards. Of course, if fuse is used for blasting, the men who split the fuse must be equipped with some type of flame-making device. These suggestions may be regarded as somewhat radical now, but they are feasible and the time will come when they will receive thoughtful consideration.

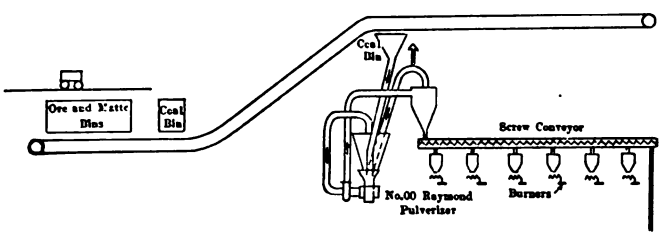
## Pulverized Coal for Use in Sintering

By E. H. Hamilton*

DURING the war the cost of crude oil for ignition of the charge in the Dwight-Lloyd sintering machine at the Midvale plant of the U. S. S. M. & R. Co. plant rose to such a figure that an attempt was made to substitute pulverized coal for the high-priced oil; the attempt was most successful.

The first experimental plant was described in the *Engineering and Mining Journal* (1919, **107**, 745). This plant, shown in the accompanying diagram, was used for determining the proper pressure and volume of air, the quantity of coal and the kind of muffle best adapted to the work.

Slack coal is delivered to one of the bins formerly used for ore. From this bin the coal is delivered by belt conveyors to a bin above a Raymond No. 00 pulverizer. The pulverizer grinds the coal, which is pneumatically delivered to a storage bin provided with a screw



Diagrammatic sketch, D & L. powdered coal layout.

conveyor, which carries the fuel to smaller storage bins, one of which is placed at the side of each sintering machine.

The fuel is fed, by a screw conveyor, into a stream of low-pressure air, which carries it into the combustion chamber under the muffle. The air is supplied by a fan formerly used for ventilating.

The Dwight-Lloyd machines delivering 95 to 100 tons of sintered product formerly required 75 to 80 gal. of oil per 24 hr.; 560 lb. of pulverized coal now does the same work. The latter fuel carries about 1 per cent water, 47 per cent fixed carbon, 8.3 per cent. ash, and develops 13,400 B.t.u.

No additional labor is required for handling the solid fuel, and the use of high-pressure air is now unnecessary. The present plant is giving highly satisfactory results.

---

## Research Graduate Assistantships

ENGINEERING Experiment Station of the University of Illinois maintains 14 Research Graduate Assistantships and two more have been established under the patronage of the Illinois Gas Assn. To these assistantships is attached an annual stipend of $600. They are open to graduates of universities and technical schools who are prepared to undertake graduate study in engineering, physics or applied chemistry. Applications must be in the Director's hands by March 1. For information, address the Director, Engineering Experiment Station, University of Illinois, Urbana, Ill.

---

## Methods of Underground Metal Mining

THE Institute Committee on Mining Methods is making an attempt to compile a comprehensive classification of mining methods and for that purpose has sent out a chart prepared by Prof. Frederick W. Sperr, of the Michigan College of Mines. This chart seemed to have such value that it is republished on the following two pages in order that it may be available to every mining engineer.

The committee desires the assistance of every member of the Institute in this work and solicits the examination of this chart and suggestions and criticisms to be sent to John E. Hodge, Chairman, 710 Security Building, Minneapolis.

If you are using some method that is not included in the scheme of classification published, the committee would be grateful for information relative to it.

---

## Cost of Making Pig Iron in Pittsburgh

THE present freight rates on two tons of ore from the Lakes to Pittsburgh (two tons of ore being needed to make a ton of pig iron) are $2.80. The Interstate Commerce Commission has been asked to approve a rate reducing the freight to $2.01½. The pre-war rate charge was $1.92.

The present aggregate of freight rates for bringing to furnace the raw materials for one ton of iron compared with the data for 1912, is as follows:

| | 1921 | 1912 |
|---|---|---|
| Rate from mine to dock on two tons of ore .. | $ 2.06 | $1.10 |
| Boat rate and unloading | 2.48 | 1.20 |
| Lake to furnace | 2.80 | 1.92 |
| Freight on 1 1/10 tons coke | 1.80 | .80 |
| Freight on ½ ton limestone | .80 | .32 |
| Slag disposal | .54 | |
| Total | 10.48 | 5.34 |

If the reduction on ore rates that is now asked be granted, the total assembly costs will be reduced to $9.69½ per ton.

---

## Tungsten in the United States

THE history of the tungsten industry in the United States, as outlined by the U. S. Bureau of Mines, is an interesting story.

In 1870, Sam P. Conger discovered the famous Caribou silver mine at Caribou, and a few months later

Civil and Mining Engineering
Michigan College of Mines, Houghton,
Michigan, November 12, 1921.

Digitized by Google

the Boulder County mine, and Caribou was erroneously heralded as the richest silver district in Colorado and one of the largest in the world. The miners and prospectors who flocked into the district soon became familiar with a heavy dark mineral, found as "float," to which they gave various names, such as heavy iron, black iron, hematite, and barren silver. In the early part of the year 1900, Conger's partner, W. H. Wanamaker, who had seen the tungsten ores found in the Dragoon Mountains of Arizona, recognized this "float" as an ore of tungsten. Conger and Wanamaker kept their discovery a secret and in August, 1900, obtained a lease for the purpose of working the tungsten placers and developing veins. By the end of the year about 40 tons of high-grade ore had been taken out, but until the end of 1914 there was no important development

By the middle of 1915 the wartime demand for high-speed tool steel, of which tungsten is usually a component, became so great as to cause feverish activity among the owners of the known Boulder County deposits.

The price of tungsten rose to unheard-of heights, $75 a unit, or more, being the quotation for nearly two months, and at least one lot is known to have been sold for $105 a unit. These high prices caused the large users to import tungsten ores from South America, and later from China; the market broke rapidly, and during the latter part of 1916, 1917, and nearly all of 1918 was fairly steady at about $25 a unit. The small demand, and the large importations and stocks held by dealers, forced the price down so that early in 1919 all of the Boulder County producers were obliged to suspend operations. As a result, there has been a strong movement for placing a protective tariff on imported tungsten ores and products.

The development of milling practice in Boulder County, the ore-dressing methods in use and the local manufacture of ferro-tungsten and tungstic oxide are described in Bureau of Mines Bulletin 187, "Treatment of the Tungsten Ores of Boulder County, Colorado," by J. P. Bonardi and J. C. Williams, which may be obtained from the Director of the Bureau of Mines, Washington, D. C.

## Coal Miners Claims vs. Facts

THE following excerpts from the *New York Herald*, of Jan. 22, 1922, tell their own story:

### A Telegram from John L. Lewis

To The New York Herald:

The position of the United Mine Workers is that they cannot live for any less than their present earnings and no wage reduction is possible after the expiration of the present agreements.

Shamokin, Pa., Jan. 21.

John L. Lewis,
*President United Mine Workers.*

### From a Speech by John L. Lewis to 2000 Anthracite Miners at Shamokin, Pa., Jan. 21, 1922

"The miners of the country are not willing to abide by a declaration made in advance of negotiations that there must be a reduction in wages in the coal industry. By what right does any one attempt to set up a power or influence to regulate our lives by merely saying wages must be cut $1 a day? We hold that this is a negotiable question about which the mine workers who are directly concerned should be consulted. It is an inherent right that the workers should have something to say as to the conditions under which they shall labor and the compensation they shall receive. We will do all in our power to avoid a conflict in an honorable way, but if that conflict does come the responsibility must rest with those creating the conditions that force such an alternative upon us."

### Special Dispatch to the Herald from its Washington Bureau

"Coal miners, threatening to plunge the country into a general strike April 1 unless a wage increase is negotiated to their liking, are earning more than workers in other principal industries. In some instances the wages are more than double those of other workers.

"The average earnings of bituminous miners range between $100 and $125 a month, according to a survey of a group of mines just made by the Department of Labor.

"The average earnings of workers in all industries range between $85 and $90 a month, according to the same survey. Labor Department officials do not rate their survey as completely descriptive for all the nation's 13,000,000 industrial workers. This is because it represents a cross section only of industry and is made up on the basis of payroll reports of some 300 concerns and corporations. But the corporations covered employ more than 1,500,000 workers, and fourteen widely varying industries are included.

"In the cotton finishing mills the average earnings are reported as slightly in excess of $60 a month. In the manufacture of cigars workers receive an average of $68 a month.

"The reports do show, however, that the coal miners' average earning power has been reduced faster in the last year than that of any other worker, with the exception of steel mill employees. The bituminous miner has suffered a loss of 27 per cent., the survey shows, while the steel worker is receiving 46 per cent. less than a year ago. Leather workers earn about 20 per cent. less and paper makers have experienced a like reduction.

"These reductions in the case of the coal miner are the result only of fewer working days. In the cases of other workers the reduction is due to reduced wage scales as well as to fewer working days. The rate of pay of the coal miners has not been changed in two years."

# Routine Mine Sampling at Butte*

By DONALD C. GILBERT

Chief Mine Sampler, Anaconda Copper Mining Co., Butte, Mont.

PRIOR to July, 1919, the sampler at each mine of the Anaconda Copper Mining Co. in Butte did his work in his own way and was responsible to the mine foreman only. At that time, the sampling at all the company's Butte mines was placed in charge of a member of the geological department and standardized methods of doing the work were adopted. These standards were incorporated in a set of instructions accompanied by blueprints representing typical conditions. The main features of the instructions were as follows:

All samples to be cut at breast height and horizontally, regardless of dip of vein, and the horizontal width reported.

A single sample to include not more than a 5-ft. width of the breast and to weigh not less than 4 lb. for this width.

Where the vein is made up of two or more streaks of different hardness or mineral content, each streak is to be sampled separately and the average value of the combined width figured. If two streaks of ore are separated by a streak of waste, which is not sampled, in obtaining the average value of the breast the waste must be figured in with a zero assay.

Drifts to be sampled in the breast after each round.

Raises to be sampled for each floor raised. Each end to be sampled separately and the average width and value of the two ends to be used as the average of the floor.

All veins cross-cut to be sampled along the side of the cross-cut, at breast height and horizontally. Where the vein strikes at an acute angle to the line of the cross-cut, the width of sample must be corrected to show the horizontal width at right angles to the line of strike of the vein.

Rill stopes must be sampled across the full mining width.

In square-set stopes, each set must be sampled separately along the line of the caps. Waste portions of the vein which are mined for filling must not be included in the sample.

In the instructions, the method of taking separate samples of individual streaks in the vein was stressed. This practice tends to produce more accurate work than would be given by one sample across the entire width, for in the latter case it is easy to include too much or too little of the higher grade portion of the vein in making the cut. Where the individual streaks are sampled and the average value of the vein is calculated on the basis of the width and value of each streak, the result is accurate for all practical purposes, but is not exactly correct if there is a difference in the specific gravity of the streaks. At times this difference may become pronounced enough notably to affect the results, but the occurrence is so rare that it is ignored. Thus it sometimes happens that a vein consists of two parallel streaks of very different type; one may be composed almost entirely of iron pyrite with high copper content, while the other may contain the usual quartzy gangue with a much lower copper content.

As a simple illustration, let us assume the specific gravity of the pyritic ore as 5 and that of the siliceous ore as 2.5. In Fig. 1 we have a vertical vein 6 ft. in width, which is also the width of the drift, composed of two grades of ore. On the left, a 2-ft. streak assays 12 per cent. Cu. and has a specific gravity of 5, and the remaining 4 ft. of the vein assays 2 per cent. Cu. and has a specific gravity of 2.5. By the usual method of figuring the average assay of the breast, we have:

$$\frac{(2 \times 12) + (4 \times 2)}{2 + 4} = 5.3,$$ or 6 ft. of 5.3 per cent. Cu.

This supposes that the total weight of 12 per cent. ore which would be broken if a round were blasted would be one-half that of the 2 per cent. ore, as the weight of each is assumed to be proportional to its width, which is incorrect. The total weight of each class of ore broken would be the same, since the 12 per cent. ore, while only half as wide as the 2 per cent. ore, has twice its specific gravity. The true assay of the ore broken in the drift will be:

$$\frac{12 + 2}{2} = 7$$ per cent., and the average assay is 6 ft. of 7 per cent. Cu.

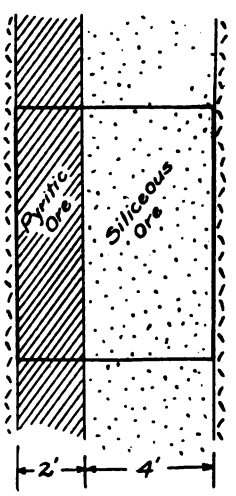

FIG. 1.—VERTICAL VEIN.

Sample cuts are horizontal as it is easier to make the cut in this direction and the figure is convenient for other work. The veins are quite steep as a rule and the tonnage in a given block of ground is figured on the basis of the horizontal width of the ore. In Fig. 2, which represents the cross-section of a vein between two levels, the usual method of arriving at the cross-sectional area of the vein would be to multiply the true width *A* by the dip length *B*. The same area is found by multiplying the horizontal width *C* by the lift *D*, both of which figures are obtained without calculation.

After standard sampling methods were adopted, the next step was to find the degree of accuracy that was being obtained by the samplers. The chief sources of error in sampling are lack of knowledge of the work at

*Abstract of paper that was awarded the President's Prize, at the meeting of the Directors of the A. I. M. E. on Oct. 21, 1921.

Digitized by Google

hand, and carelessness. Careful training will eliminate the former but the latter must be constantly combatted. At times, the sampler must temporarily hold up the work of miners who have little drilling time left and they do not enjoy the delay; so he gets his samples in a hurry. And when a raise through a 200-ft. lift gets up a score of floors from the sill, and the air is warm and the rock is hard, he often finds it convenient to get his samples in the shortest possible time. In addition, each sampler has his own personal factor, whereby he tends to include too much or too little of the richer portions of the ore, even when working with the

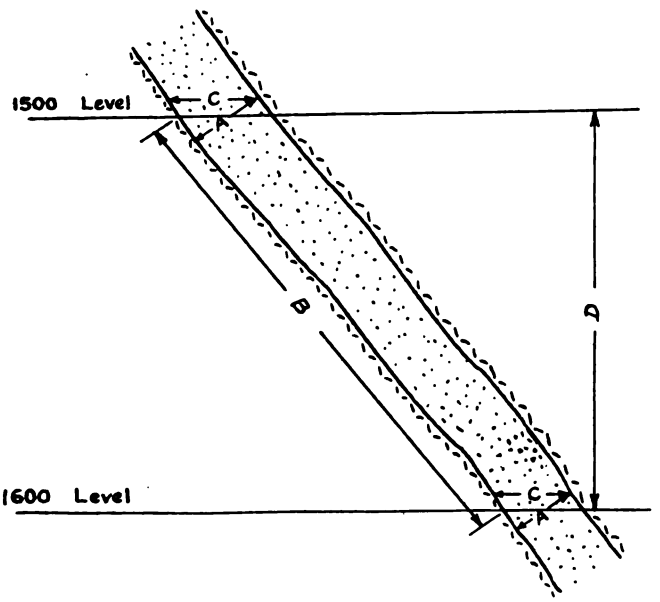

FIG. 2.—CROSS-SECTION OF VEIN BETWEEN TWO LEVELS

greatest care. This error is cumulative, but if it is determined the sampler can be coached to eliminate it. For this reason, rating tests were made with each mine sampler and an approximate determination of his personal factor was made.

## RATING TESTS

Each man was rated on the results obtained in a series of check samples taken under varying conditions. On entering a place to be sampled, the exact width of sample to be cut was first decided, and the mine sampler and chief sampler each cut an independent sample between these limits. If any error on the part of the mine sampler was observed the fault was explained to him at the time, but the sample was retained in the series. Any probable source of error from unconscious salting was also explained where the conditions were met. It was not expected that the number of samples taken would be great enough to serve as a safe basis for the determination of the sampler's personal factor to a close degree, but it was believed that where the mine sampler's results were in the majority of cases higher than those of the chief sampler, or were generally lower, as the case might be, his approximate percentage of error could be determined. Also, the comparison of one unknown factor, the mine sampler, with another unknown factor, the chief sampler, could decide nothing unless means were found to check the accuracy of the latter.

It was decided at the start that the average results that would be obtained by the total number of samplers in question, if each were to cut an independent sample across the same breast of ore, would be very nearly correct but would probably lean toward slightly high results. This assumption was made because of two observed tendencies among the samplers. The first is the tendency of some men to take too much of the high-grade portions of the vein and fail to include a representative amount of the lower grade material. Since good ore is the commodity sought for in mining operations, it is a normal tendency for a man to focus his attention on it. The second observed tendency is for some samplers to keep too far on the safe side. Dilution of ore with waste, in mining, frequently runs the grade down to such an extent that the foreman insists that the sampler is doing poor work and showing greater values than are actually present, so that the sampler finally adopts the plan of including an excessive amount of poor material in his sample. As a result of an estimated balance of the opposing factors, it was decided that the average sampler was probably getting too high results.

In the determination of the personal sampling factor of each man, the results of the chief sampler were assumed to be 100 per cent. correct, and the sampler's factor was represented by an index number corresponding to the ratio of his average results to those of the chief sampler. At the completion of the work, it was found that the average index number of the eighteen men in question was 107, compared to the assumed 100 of the chief sampler, which was accepted as a check on the accuracy of the latter, since, as stated above, it had been previously expected that the average results would be slightly high.

In this work an attempt was made to sample as many different types of vein as possible. While the rule was to sample each individual streak, the streaks themselves were often of such description as to make close sampling difficult. Thus in some instances a streak of good ore, three or four feet in width, would contain several minor streaks of alternating high- and low-grade material. In these the high-grade ore was in some instances harder, and in others was softer, than the low-grade material, in other cases the valuable minerals occurred in a very spotty manner. Places of this description were considered ideal for the purpose at hand as they made it possible for the sampler to demonstrate his ability to make a uniform sample cut regardless of the grade of material at varying points along the cut. Careful record of the character of the vein sampled, its hardness, distribution of values, and other data was made for each sample.

Digitized by Google

Tables were compiled, in which each sampler was given an index number. In one case, this index number was very high, 147. The ratios of this sampler's results to those of the chief sampler varied in individual cases from $^{125}/_{100}$ to $^{180}/_{100}$, the average being $^{147}/_{100}$. There was no doubt that this man was getting much too high results, and close observation showed that he invariably took too large a proportion of the high-grade ore, which, in most cases, was softer than the leaner portions of the vein. Other samplers were also found to be getting too high results, on the average, and in each case a careful observation of the man's operations and an explanation of the probable causes of his error was made; a second series of samples showed decided improvement. When the sampler's index number was between 90 and 110, his work was considered satisfactory, unless the variation of his individual samples had been too great.

### Records and Reports

From the rating tests, it was decided that certain samplers had a tendency consistently to get too high or too low results, and that this personal factor had been approximately determined. It was found, also, that certain samplers were so erratic in their work that no normal tendency was apparent in the results they obtained. The peculiarities and failings of each man, therefore, were studied and corrected as much as possible, and occasional series of check samples were run to make certain that the quality of the work was being improved.

Each day the sampler receives an assay return, in duplicate, on the samples sent from the mine on the preceding day; one copy of this, with the necessary data concerning the position of the samples, is put on file in the shift-bosses office, and the assays are then entered on the sampler's own records. A daily report is made out and sent to the geological department, showing the location of each sample and giving the average value of the ore exposed in each working place. At the geological department, the chief sampler records the assays in a loose-leaf book in which one sheet is kept for each working place. The report is given to the geologist for that particular mine, which enables him to keep in touch with each day's development.

One day of each week is " contract-measuring day," and at this time all advances for the week are given to the sampler by the engineers. The sampler makes a weekly advance report which shows the advance, total length and average assay and width of ore exposed in each drift and raise, and the average width and value of all veins cross-cut. If new development working places have been started during the week, their location is given on this weekly report. Copies are sent to the mine superintendent, mine foreman and the engineering and geological departments. At the end of each month a summary of the preceding four or five week's work is made out in similar manner. Standard forms are used for all reports.

In the geological department, a file of weekly and monthly advance reports is kept, but as the task of finding the records of any working place in this file would be long and tedious, a graphical record or "assay-curve system" has been adopted. In this system, the assay record of each drift and raise is plotted on a card of heavy cross-section paper, and the cards for each mine are filed in the numerical order of the working places; cross-cuts are not included in the system. These cards are posted from the weekly advance sheets. For the drifts, the horizontal scale is 1 in. = 50 ft. of drift-length, which is the same scale as the geologic maps of each mine level. The assay curve is plotted to the vertical scale of 1 in. = 10 per cent Cu. (Zn, Pb or Mn) and 10 oz. Ag, and colored inks are used to differentiate between the various metals. The width is shown by figures and represents the average width of ore exposed during the week's advance, as the curve represents its average value. Raises are plotted in similar manner but at right angles on the cards to the direction of the drifts. The assay curve for each drift and raise is kept on a separate card and placing the card under the fifty-scale geologic tracing shows the data in the most convenient position for use.

### Results

Sampling, at its best, is far from being an exact science. Two trained samplers, equally proficient and working with care, will often obtain from the same breast samples that will differ by 25 per cent. or more. For this reason single assays must always be discounted; they cannot be accepted as correct to a closer degree than has been found to apply under the circumstances. Where a competent man has taken a number of samples along a drift or raise, the average of the lot may be accepted as very close to the true value of the ore exposed, since his errors are compensating, not cumulative. A check on this fact has been made at various times by means of duplicate samples taken through 100 ft. or more of drifting, the average value of the ore drifted through being obtained separately for each set of samples. The greatest variation found was 4.2 per cent. Cu. and 3.0 oz. Ag, compared to 4.4 per cent. Cu. and 3.1 oz. Ag. in 93 ft. of drifting.

It is not claimed that investigation and standardization of sampling methods in use in the Butte mines of the Anaconda company has resulted in obtaining representative samples of extreme accuracy, but it has resulted in definite knowledge of the degree of accuracy that was actually being obtained and in bringing this within the allowable limits of variation. Finally, the maintenance of this standard requires constant supervision and frequent duplication of each sampler's work.

# Undesirable Diversity in Non-Metallic Mineral Products*

By OLIVER BOWLES

Quarry Technologist, Bureau of Mines, Washington, D. C.

SUPERFLUOUS varieties and standards which are meriting the critical scrutiny of the manufacturing industry have a special significance in the non-metallic mining industries, where many of the final or intermediate products are manufactured at the mine or quarry. Such processes of manufacture must be considered an integral part of mining in its broader sense. Improvements may be either elimination or standardization. The chief requirement of elimination is an agreement between consumers and producers based on facts deduced from statistical data.

Standardization is much more complex. Standards may be established only when a very thorough knowledge has been gained of the physical and chemical properties of the products, and the requirements of consumers. The activities of the Bureau of Standards are largely directed toward such determinations.

Paving-brick manufacturers, together with highway engineers, representatives of certain engineering societies, and Government bureaus, have agreed that of the 66 styles of paving brick on the market 11 only are essential and 55 are superfluous. Steps have been taken to reduce the output of all but the 11 standard types.

It is customary for manufacturers of structural slate to prepare it in sizes specified by builders and architects. Thus the material cannot be manufactured in advance and the result is irregular activity of mills, delays in filling orders, etc. To improve this condition, the Structural Slate Co. has issued a series of pamphlets giving complete specifications of structural slate for various purposes. Architects find it so much easier to order slate from these sheets that standard sizes are specified in preparing plans for new structures.

Slate switchboards are usually manufactured after the order has been received. One manufacturer claims that 80 per cent. of all switchboards are of standard sizes, and he keeps such sizes in stock. The facility with which orders may be filled from stock, and the improved quality of seasoned switchboards, will undoubtedly influence electrical companies toward a more uniform standardization in size. Simplicity could be further attained by the elimination of minor irregularities in style; for example, in the beveled edges.

Similar tendencies exist in the structural block sand, gravel and crushed-stone industries. Limestone quarrymen have found it advantageous to establish a standard size 8 by 4 by 4 ft. for mill blocks, and large piles of such blocks are stored for seasoning before shipment to stone-cutters. Concrete blocks, artificial stone, terra cotta, and similar types of molded building blocks are gradually being standardized.

Producers of sand, gravel and crushed stone have been greatly handicapped by the varied requirements of consumers. For the past two years various organizations have been striving to establish standard screens, and to eliminate all unnecessary sizes. A notable step in this direction is the preparation of a set of tentative specifications, issued in 1920, by the American Society for Testing Materials working in coöperation with the Bureau of Public Roads.

Feldspar is not standardized as to either grain sizes or purity. No. 1 spar is variously defined as dental spar only, as pure feldspar of any kind, or as a mixture of feldspar with a small percentage of quartz. Some limit No. 2 spar to 5 per cent. quartz, while other consumers classify as No. 2 a spar that contains as much as 25 per cent. quartz. Specifications may call for fixed percentages of soda and potash, or such requirements may be omitted.

The standardization of mineral fillers is practically untouched. Such standardization, accomplished through a comprehensive study of the subject, would not only promote better manufacturing processes, but would be of material benefit to producers.

The classification of mica is very confusing, for standards differ not only in different countries but in different parts of our own country. The most widely known domestic standard includes punch, circle, and rectangles of various sizes. Canadian phlogopite is graded in sizes of rectangles that differ from most of the United States standard sizes. India mica is widely used in the United States, and it is classified not on the basis of the sizes of rectangles obtainable, but on the basis of the area of good mica in the sheet, for which 10 arbitrary grades have been established.

In quality, domestic mica is classed as clear, slightly spotted or stained, and heavily spotted or stained. No definite boundaries have been fixed for these grades. Mica sold as "clear" is often spotted, and this has prejudiced users against domestic mica.

# Correspondence and Discussion

## Licensing an Example of Unnecessary Laws

I REGRET that I could not be present at the meeting of the New York Section but desire to state that I am unalterably opposed to any licensing law for mining engineers.

I do not believe that it will be a protection or benefit to the public or to the profession. Such legislation is merely an example of the unnecessary laws with which American life is now being hedged in. It will mean an expense to the engineer without any return and a further expense to the general tax payer who will be required to pay for any deficit not covered by the fees collected. The only advantage accruing from such legislation will be to the professional politician who will thus obtain further plums to be distributed among his constituents.

S. H. BALL.

New York, Jan. 11, 1922.

## Licensing Engineers Not Analogous to Licensing Doctors

THE chief arguments that I have heard in favor of licensing engineers are that it is necessary in order to put us on the same plane with lawyers and physicians and that it is desirable in order to prevent overcrowding of the profession.

As regards the first point, I do not feel that the profession of engineer is at all akin to that of the doctor or lawyer. From the very nature of their practice the two latter are much more in one place than is the engineer and a state license is practically all that they require. If one could be at all sure that one state license was all that one required, it would be a small matter, but where one might be forced to take out 48 state licenses at the beginning of each year, for fear that he might be called upon to practice in those states during the year, the matter would become exceedingly burdensome. I recall one of our members, when this matter was under discussion nearly a year ago, going over his books and finding that he had actually worked in 28 states in the calendar year 1920. I remember that I myself was actually at work in 11 states during that year. Probably neither of these is at all unusual among our members.

As regards the second reason given, to avoid overcrowding the profession, most of us have never been willing to stand for labor-union principles and this seems to be the adoption of their foremost tenet. I myself feel that this is an utterly indefensible excuse; that if we are afraid of competition from overcrowding we had better get out of a profession where new ideas and new men should be welcome.

In conclusion, I am in favor of getting out and fighting engineer licensing bills, both as regards the passing of new ones and looking toward the repeal of the present one in New York State, and I shall be glad to contribute to any campaign to do this.

D. M. LIDDELL.

New York, Jan. 11, 1922.

## Licensing Engineers and Architects

YOUR treatment of the above-mentioned subject in the January issue of the magazine., MINING AND METALLURGY, has my active and earnest support. My work during the year takes me into more than half of the states of the Union, as well as Canada, and I am opposed to impositions placed upon mining engineers by "mistaken and self-styled" engineers who are fostering this legislation.

It now seems that a certain growing political organization which has for its purpose the cleaning up of politics, interesting business men in politics, as well as standing for nothing short of red-blooded Americans in office, may be able to do something to have mining engineers excluded from provisions of the law, especially in the state of Minnesota. The engineering societies of the state all support the registration, and anyone who disagrees is branded a "Bolshevik."

If all mining engineers could be organized for concentrated attack, aided by representative voters of the realm, that part of the law relating to mining engineers may be repealed, as an initial step.

Appeals to register in this state have been made more than once, which signifies lack of support, similar to that of New York, where "250 applied out of 30,000."

A MINING ENGINEER IN POLITICS.

Duluth, Minn., Jan. 13, 1922.

## Licensing Not Inevitable

IN CONNECTION with the meeting of the New York Section of the American Institute of Mining and Metallurgical Engineers, Inc., held last night to discuss the licensing of engineers, I desire to place myself on record in opposition thereto. As a member of the American Society of Civil Engineers, I appeared some time ago before the committee appointed to investigate this matter, and gave as my opinion that

Digitized by Google

the only people who would benefit by the licensing of engineers would be those administrating the fees collected from engineers, as I did not consider licensing would be of value to the engineer, to the state or to the public.

While at the start the Licensing Board may be composed of representative engineers, I doubt if this would continue for any length of time, and eventually the Board would be considered a place to reward political services.

My own opinion is that the principal engineering societies, instead of compromising with those who advocate licensing, should fight it to the bitter end, for I believe, with a united front, the laws already passed can be repealed, and the passing of similar laws in other states can be prevented. The more I study the question, the less I am inclined to agree with some of the civil engineers who consider that licensing is inevitable, and therefore engineers should join and see that a proper law is formed instead of trying to oppose it.

It is possible, of course, that my opinion may be erroneous and may be based on insufficient data. For this reason I suggested to the above committee, and now suggest to you, that a letter should be written to every member of the principal engineering societies living in, or doing business in, a state where there is a licensing law, asking him two questions:

1. Whether, by experience, licensing has justified itself;

2. If not, whether it should be amended or repealed.

I am a great believer in the superiority of fact over opinion, and should the majority of responses indicate that licensing in practice has worked out successfully, no one would be more ready than myself to change my opinion.

PHILIP W. HENRY.

New York, Jan. 12, 1922.

---

## Licensing Engineers Will Not Protect the Public

I AM sorry that I cannot attend the meeting of the New York Section this evening. The subject that it is going to discuss is of great interest and importance. I think that the movement toward the licensing of engineers ought to be checked; and there should be, furthermore, concerted effort for the repeal of such legislation in the states that have enacted it.

The fundamental objection, I think, pertains to the manifest difficulty of defining the engineer. Engineering was formerly divided into two heads, *viz.* military and civil. With the development of our civilization, the engineers in civil life began to subdivide themselves naturally into mechanical engineers, mining engineers, electrical engineers and so forth. Later on these great groups became the subject of further subdivision, with the result that at the present time an engineer may be experienced in a certain kind of engineering work without knowing much about other kinds even under his own generic heading.

The licensing of men as engineers by the state would manifestly be no protection for the public, for while a man so licensed might be a competent land surveyor he might be incapable of building any kind of a bridge, and still less of equipping a mine. Yet, a state license as an engineer would sanction his practice in any work for which he could find anybody to employ him. Instead of this being any protection for the public it would probably result in the ignorant being more easily duped. The consequences of such legislation may therefore be expected to be mischievous rather than salutary.

On the other hand, engineers who are really such, practicing honestly in their specialties and recognizing their own limitations, would find themselves greatly hampered, especially when their work extended beyond the limits of their domiciliary state. They would be subject to considerable license fees, perhaps in numerous states, they would be the victims of discordant laws, often expressed in uncertain ways without as yet any interpretations by the courts, and they would become the subjects of great irritation generally.

I do not think that the argument that engineers should be licensed like other professional men is meritorious. The analogy is not close. The medical man, for example, comes directly in contact with the public and the latter needs protection against quacks. It is said that there are 200,000 engineers in the United States. The great majority of these are men who are employed by senior engineers, by large firms or by corporations, who know far better the capacity of the men whom they employ than any licensing board can possibly know. The relatively few who come in contact with the public do so in superior ways, and about the last thing in the world that their clients would ask of them would be the question whether they have been duly licensed.

The farmer who wants to have his land surveyed, who wants to have the work done properly, and who perhaps is not well acquainted among engineers who do such work may be benefited, by having it done by some one with a state certificate. I do not know how that might work out, but it is the only contact between engineers and the general public that I think of; that is to say, the only contact unless plumbers and mechanics of their ilk are to be considered as sanitary engineers, heating engineers, etc. If so, I should say let them be licensed, but let it be as "sanitary engineers capable of doing plumbing work," or under some such specification.

However, the idea of undertaking to license engineers broadly seems to me to be rather ridiculous. I do not think that it is necessary to elaborate further upon the points that I have made in this communication, for the mere statement of them will indicate to the members of the New York Section whither they lead.

# Abstracts of Institute Papers

All of the following papers will be presented at the New York Meeting, Feb. 20–23, 1922, and will be printed in full in the Transactions.
A copy of any of these papers in full will be sent free to members on application, for which a request blank is furnished on page 32 of Advertising Section.
Discussion of papers invited.

## Underground Fire Prevention by the Anaconda Copper Mining Co.

By E. M. Norris, Butte, Mont.

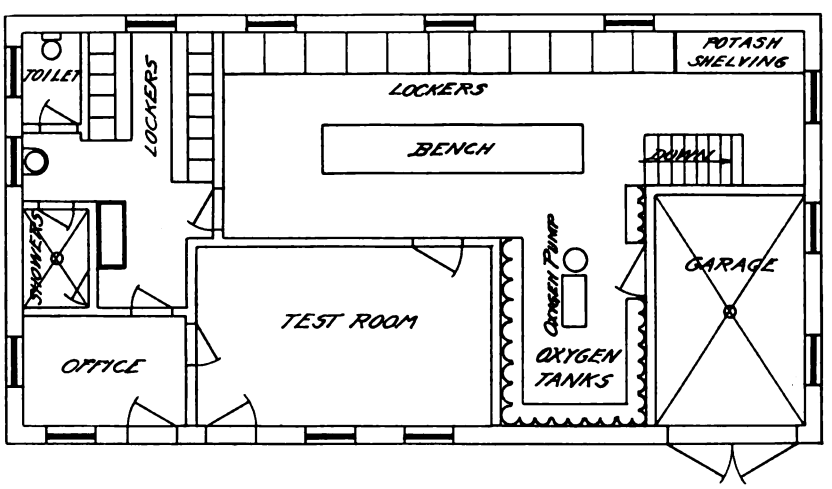
DURING the winter and spring of 1917, an unprecedented number of underground fires occurred in the Butte district. With one exception, these fires were caused by the failure of electrical equipment.

Five local conditions that contributed toward a heavy fire risk were: (1) The heavy continuous timbering necessary for mine supports; (2) the strong ventilating pressures in the shafts and main airways; (3) the subsidence and faulting movements in the country rock, which ruptured cables and displaced trolley and lighting wires; (4) the strongly acid mine waters, which quickly developed any weak points in the electrical insulation; (5) oxidation in old stopes containing large amounts of timber.

In the summer of 1917, a comprehensive plan of fire prevention was begun by the Anaconda Copper Mining Co., comprising fireproofing, remodeling and strengthening electrical insulations, extension of underground water system, control of ventilation, maintaining efficiency of fire-fighting crews, and reorganization of fire patrol.

In considering fireproofing, some method of applying a durable coat of fireproof material to the mine timbers was needed. The first experiments were made with a plaster composed of one part cement, one-half part fireclay, and three parts sand, applied by hand over herringbone metal lath. This was too soft and friable for traveling ways, where it was subject to abrasion. The cement gun was tried out with a three to one mixture of sand and cement. A ½-in. coating of gunite applied over poultry netting or metal-lath reenforcement proved to be durable and fire resisting.

Preparations were made to fireproof the tramway of No. 1 hoisting shaft. This was a four-compartment shaft, 2475 ft. in depth; it was lined with framed shaft sets of 12-in. fir timber; the sets were 7 ft. by 18 ft. 10 in. over all, and were spaced 5 ft. on centers. The sets were lagged with 2-in. pine plank, placed against the rock walls. The timbers and lagging were covered with a ½-in. coating of cement, applied with the cement gun over 27-gage diamond-mesh metal lath. The fireproofing operation was completed in the fall of 1917. Because of the success of this operation, it was decided that the twenty-four main hoisting shafts operated by the Anaconda company in the Butte district, not already so, should be made downcast shafts and similarly fireproofed; also that the same treatment should be given all surface tunnels carrying steam, air, and electric power from plant to mines.



PLAN OF TRAMWAY RESCUE AND TRAINING STATION; STOKEROOM FOR SUPPLIES IS IN BASEMENT AND CLASSROOM IS ON SECOND FLOOR.

Twelve type N-I cement guns were procured and the work pushed as fast as operating conditions would allow. One or more shafts at a time were withdrawn from ore production, retimbered where necessary, and fireproofed under the direction of the mine foreman. Each foreman selected a crew, from among his shift bosses and shaftmen, who were trained at one of the mines where fireproofing work was in progress. The work was carried on continuously by three 8-hr. shifts. The crew for each shift consisted of one shift boss, six shaftmen, who nailed on the metal-lath reenforcement, two nozzlemen for the cement gun, two runners for the cement gun, station tenders, topmen, etc.

Regarding the details of the gunite work, some general conclusions may be summarized. Poultry netting makes satisfactory reenforcement for covering wooden surface structures of continuous plane sur-

Digitized by Google

faces, such as buildings and ore bins; expanded-metal lathing is to be preferred where much fitting is necessary, as on underground timbering. A gunite covering ½ to ¾ in. thick on wooden surfaces is sufficient for fireproofing purposes. The sand should be clean and should be screened through a screen four or five meshes to the inch. If the sand is very dry, it does not mix well with the cement; 6 to 10 per cent. moisture is best. Moisture in excess of 15 per cent. is liable to block the material hose. A mixture of three parts of sand to one of cement is best.

The Tramway shaft has had 3½ yr. continuous service in ore production since the fireproofing work was completed. A recent inspection of the shaft showed that the timbers from the surface to the 1600-ft. level were 92.5 per cent. covered with gunite; from the 1600-ft. to the 2800-ft. level, the timbers were 85 per cent. covered with gunite. The depreciation of the gunite is due to falling rocks from overloaded skips.

## Bureau of Safety of Anaconda Copper Mining Co.

By C. W. Goodale and John L. Boardman, Butte, Mont.

THE motives behind the organization of the Bureau of Safety were twofold. First, there was the policy of the company toward its employees, which was one of fairness and consideration for their welfare and which entails the prevention of injuries; second, in order to prevent injuries, a study of their causes was essential, and this study could be made only by a thorough systematic classification of accidents, which required a special department to form and carry out the plans.

The Bureau of Safety was organized to begin operation Jan. 1, 1914, but practically all of the first year was and spent in collecting data, making plans, etc. This department is semi-independent of others and reports directly to the president and general manager. It consists of the president of the company and the managers of the following departments: mines, Washoe Reduction Works, Great Falls Reduction Works, coal department, lumber department, B. A. & P. railway, and the chairman of the Bureau of Safety.

Working under this group is the General Safety Committee consisting of the manager of mines, as chairman, the general superintendent, two assistant general superintendents, and the heads of the following departments: mechanical, geological, sampling works, framing plant, and purchasing, as well as the safety engineer.

Operating under the General Safety Committee are the group safety committees, consisting of the Anaconda group of mines, Boston & Montana group of mines, zinc group of mines, Washoe reduction works at Anaconda, B. & M. reduction works at Great Falls, coal department, lumber department, and the B. A. & P. railway. Each of these group safety committees was in charge of the superintendent or manager of the group represented and the committee consisted of the foreman of the mines or works that the committee served, as well as the safety engineer.

These foremen and superintendents had met regularly for the purpose of discussing costs, efficiency, and methods, therefore it was only necessary to add, at these regular meetings, the discussion of safety matters.

On the completion of the work of organization of the new bureau, an inquiry as to the causes of accidents was made. It was decided to adopt the shifts as a basis upon which to compute accident rates, and ten thousand shifts was made the unit, partly because it is an easy figure to work with in the decimal system and partly because it is probably near the maximum number of shifts that a man might work underground in a life time. An accident rate thus based shows the chances a man has of being injured in a lifetime of work.

In 1913, the company decided to award cash prizes for accident prevention, to the foremen having the lowest accident rate per 100,000 shifts, but this offer was discontinued, for various reasons, after two years of operation.

At first the Bureau of Safety paid little attention to safety rules; the general manager compiled a four-page pamphlet of fundamental rules and a copy was given to each employee. The idea was to keep down, as much as possible, the number of rules but to enforce those made. As the work developed and accident records began to reveal dangerous practices, placards, either pictures or printed matter, calling attention to the danger were posted about the mines and works. Many of these placards have become rules in effect. Later these rules were assembled and are now ready for publication in book form; they are given in full in the paper.

It was early realized that, while exact enforcement of safety rules and holding foremen responsible for accidents would do much toward the prevention of accidents, the greatest factor was the interest taken by the workmen themselves. In order to get the case before all employees in the proper light the publication of *The Anode* was begun in January, 1915. Supplementing *The Anode*, a complete set of motion pictures, showing the numerous operations from the mining of the ore, in Butte mines, to the making of wire bar, at the Great Falls smelter, with safe practice and safety slogans interspersed and emphasized by red film, were made and have been shown free at various times to employees. There are twelve reels; about 9000 ft. of film.

It is fortunate that the originators of the Bureau of Safety did not proceed on the basis of cost alone, for it is feared, though not definitely known, that unless the value of safety work, from the standpoint of morale, is considered, the balance would not show favorably. However, it can be definitely stated that considering costs and balancing against them all the various values

Digitized by Google

and advantages of the safety campaign, the department has paid immeasurably, and we recommend to anyone desiring to go into the safety work that the key to success is sincerity on the part of those so engaged; not from a purely financial standpoint but rather from a desire to alleviate the suffering and minimize the loss to workmen due to industrial accidents.

## Efficient Ventilation of Metal Mines

By D. Harrington, Denver, Colo.

EFFICIENT ventilation of metal mines consists in having such complete control of air currents that there is always supplied at places where men work sufficient moving air to allow working at maximum capacity without injury to health; and, in case of underground fire or of surface fire in the vicinity of mine openings, control of underground air currents which may be quickly reversed or sent into or excluded from any region and fire fumes confined to part only of the mine workings.

After several years study of miners' consumption, the writer is convinced that long continued breathing of air impregnated with large quantities of any kind of finely divided dust, such as is found in a large number of the working places of our mines, will ultimately produce some respiratory disease, whether it be asthma, bronchitis, or phthisis; and the progress of these diseases is hastened if there are also present high temperatures, high humidities, or harmful gases or if there is present (and allowed to remain to be breathed) large quantities of the finely divided dust when air temperatures are low, hence favorable to maximum performance of work with accompanied maximum breathing into the respiratory passages of the harmful material. It is generally accepted that coal miners under the age of fifty are much more free of these respiratory diseases than are metal miners, and it is practically certain that this immunity of the coal miner is due largely to the fact that working places in coal mines are much better ventilated than those of metal mines. A close study of dust conditions in metal mines convinces the writer that, except for preventing formation of dust, the most efficient preventive of undue dustiness of air breathed by metal mine workers is the coursing of adequate currents of air past the places where dust is produced or is being thrown into the air—thus replacing the dusty air with dust-free air.

Failure to remove poisonous fumes from detonation of explosives at confined working places, reduces vitality of workers; not infrequently these fumes cause death. Failure to remove smoke from working faces prevents the worker from properly inspecting overhead conditions and thus preventing many accidents. With $CO_2$, nitrogen, or, as occasionally occurs, the explosive methane, inadequate ventilation and knowledge of gases usually results in hospital cases or fatalities, or possibly in occasional closing of the place or the entire property until outside aid or information may be secured.

After about five years spent largely in a study of metal-mine ventilation, supplementing over fifteen years spent in more or less intimate contact with ventilation in coal and, to a less extent, in metal mines, the writer believes that no mine (coal or metal) can be efficiently ventilated without the use of mechanical equipment (especially fans). While there are probably well-ventilated mines with natural currents (that is, without the intervention of fans or other mechanical equipment), he has never visited a property of that description.

Each mine should have at least one fan, of comparatively large capacity, to control main underground air currents. Preferably, this fan should be located at the surface, in fireproof housing, and should be so arranged that the direction of currents may be reversed in a very few minutes by manipulating a few doors. The most up-to-date practice is the installation of electrically driven, high-speed fans; and where gases, such as $CO_2$ or nitrogen, come into workings from strata, it may be desirable to keep underground air under pressure. Local conditions will determine whether the fan should be operated as a suction or as a force unit, but, in general, the main fans exhaust foul air from mine workings. As a rule, it is desirable that the main operating shaft or tunnel be an intake and that the fan should not be located at the main operating shaft or tunnel. Where possible to arrange, the main operating (haulage) shaft or tunnel should not be used as a main air course, but this recommendation can seldom be carried out. Large mines should have approximately 15,000 cu. ft. per min. for each 100 men employed, if the underground rock and water are cool, and at least that amount per 50 men if the workings are over 80° F.

Metal-mine officials rarely recognize the necessity of sealing abandoned workings in order to force air currents to live workings. The practice of allowing intersecting openings,—horizontal, inclined or vertical,—to remain open to air circulation, or leakage, dissipates air into places where it becomes impregnated with fungus spores, $CO_2$ from timber decay, increased temperature and humidity and possibly dust. Frequently, it is not needed in the places where it goes (though needed badly elsewhere) and after having become vitiated passes into places where men work. Closing places that are not being worked would frequently result in the recovery of much material that is now lost and would remove a common source of danger to life and limb in metal mines in addition to greatly aiding ventilation.

A pipe introduced on the Rand for ventilating headings has some advantages over galvanized-iron and canvas pipe, according to S. de Smidt. This pipe is

Digitized by Google

made of concrete, reenforced with wire netting, in 6-ft. or 8-ft. lengths, and is 1 in. thick for 12-in. pipe. Sleeves about 4 in. wide are used, to cover the joint between the pipe; soft clay is pressed into the joint and from time to time inspected and tightened. The sleeves have the advantage of permitting gradual bends, and if necessary, special curved shapes may be made. The pipe is laid on the floor, which is another advantage, as it can be covered with loose material and thus protected from falls of rock. The greatest advantage, however, is that, the concrete being a non-conductor, there is less heating of the air in traveling long distances to a hot level. The recently perfected ventilation installation at the Colorado mine at Butte, Mont., cost over $70,000, but shortly after its installation it was found that the saving in electrical power for compressing air was about $18,000 per year. In addition to several indirect benefits realized, the average efficiency of all underground employees was increased at least 50 per cent. In a private conversation with the writer, Mr. Bruce stated that with the mine working to its normal capacity (two full shifts), the various savings effected through the ventilation installation would readily return its entire cost of over $70,000 at least once, and probably twice, annually.

This paper has been able to touch on only a comparatively few points in connection with ventilation of metal mines, considering safety and health only to a slight extent, with intent to concentrate on suggestion of desirable methods to obtain efficient metal-mine ventilation, with a slight amount of attention to costs and results translated into dollars and cents.

---

## Ventilation of Butte Mines of Anaconda Copper Mining Co.

By A. S. Richardson, Butte, Mont.

THE necessity for mechanical ventilation of the Butte mines of the Anaconda Copper Mining Co. is due to a number of causes, all of which are incidental to the depth at which mining operations are now carried on. The main object to be accomplished, of course, is the reduction of the temperature and humidity of the air in the working places. Ventilation fans, both surface and underground, have been used for many years, but increasing depth has made the problem much more difficult. Further improvement in both ventilation equipment and methods, therefore, became necessary; and it is the purpose of this paper to describe the work planned and done under the improvement program.

When operations are conducted at a normal rate, about 10,000 miners are employed on two shifts, so that about 5000 men will be underground at one time, but as ventilation is necessary to reduce high temperature and humidity due, mainly, to natural causes, the quantity of air per man per minute is not a governing consideration in determining ventilation requirements.

Results obtained by various investigators indicate that the bad effects of a high $CO_2$ content in the air are not so great as has been generally supposed, provided that temperature, humidity, and air-movement conditions are such that excessive heat is removed from the body. In general, the air in the Butte mines is of sufficiently good quality, and only measures for the reduction of temperature and humidity, or increase of air movement, are necessary. The general subjects of mine resistance and coefficients of frictional resistance to the flow of air have been quite fully discussed, but wide variations occur in the figure given. By far the greater part of the determinations were made in coal mines, and almost nothing was available that had any bearing on the resistance of such entirely dissimilar workings as are found in metal mines. For these reasons, it seemed advisable to get more accurate information in regard to the mines directly affected by the work to be done, so resistance determinations were made of all important types of air courses.

Concrete water boxes for air shafts, which fit into corner of shaft compartment and offer minimum resistance to flow of air.

In practice, the static orifices of Pitot tubes were placed at measured distances apart in the shaft, drift, or crosscut, where the determination was to be made and were then connected by air-tight tube or hose to the U gage on which the difference in static pressure was to be noted. Velocity readings were then made with both Pitot tube and anemometer, and friction coefficients figured from the data obtained. For this purpose it was, of course, necessary to use workings in which there was a high velocity of air movement.

The coefficient $K$, which expresses, in pounds per square foot, the pressure necessary to overcome the resistance offered by 1 sq. ft. of rubbing surface at an air velocity of 1 ft. per min., as thus determined, is given for the following types of mine workings. In all cases, the area used in making the calculations was the

Digitized by Google

clear area of the air course inside main timber, and the rubbing surface was assumed to be that which encloses the clear area.

For rectangular shafts of two or more compartments with open timber framing, from 0.000,000,007,2 up to 0.000,000,009,6; variations are dependent mainly on the condition of the timber, such as lagging.

For rectangular shafts in which each compartments is a separate smooth surfaced duct, from 0.000,000,001,4 up to 0,000,000,002,3.

For timbered drifts and crosscuts, about 5 by 7 ft. in the clear, from 0,000,000,007,7 up to 0.000,000,010,9; variations are dependent on whether the air course is straight or crooked.

For untimbered crosscuts, from 0.000,000,003,1 up to 0.000,000,004,4; variations in this case are also dependent on whether the crosscut is straight or crooked.

For the manway compartment of raises, almost any figure from 0.000,000,025 upward may be obtained, dependent on the condition of the raise.

These figures are based on gage readings that ranged from 3 to 15 in. and are believed to be fairly accurate, considering the limitations of the instruments used and the character of the problem. It was possible to note that the variations in resistance caused by the passage of a cage through the section of the shaft upon which the determination was made, also by a man standing and walking in opposite directions in a drift and by a mine car standing in a crosscut, the last being equal to about 40 ft. of the crosscut.

Nevertheless, as all determinations made with either Pitot tube or anemometer depend for their accuracy on the assumption that the flow of air takes place in straight lines normal to the plane in which the instrument is held, serious inaccuracies must occur because this assumption is unwarranted by fact. Nothing beyond an approximation in measurement is, therefore, possible, and accuracy is in the greatest degree dependent on the care used in making it.

In confined places, such as dead ends on crosscuts, drifts, or raises, the heat generated by blasting and lights and that given off by men's bodies raise the temperature of the air. Ventilation of such places is necessary to drive out powder smoke and maintain a supply of good air and to reduce temperature and humidity. For this service small blowers are used to force fresh air from the nearest source of supply, through canvas pipes, to the working face.

Inspection of ventilation conditions, together with the duty of making recommendations for their improvement, is entrusted to a ventilation and safety engineer at each mine. He is employed under the direction of the mine foreman, but to act in ventilation work in coöperation with the ventilation engineer. Repairs and renewals of canvas pipe and blowers, and the installation of doors, or other details necessary to carry out the ventilation system, are made on his recommendation to the mine foreman. Monthly reports made to the ventilation engineer include: A record of the temperature and humidity of the air at every working place in the mine; the conditions existing at all places ventilated by blowers and canvas pipe, with a description of the equipment used and its state of repair; recommendations in regard to improvements or other matters needing attention.

As a matter of convenience in recording information on the print the following conventional signs have been adopted:

Air moving upwards, entering the level.

Air moving upwards, leaving the level.

Air moving downwards, entering the level.

Air moving downwards, leaving the level.

Bars over the foregoing signs indicate that the air is not coursed directly to adjoining levels. The mine numbers of raises, or other working places, are given when necessary.

Filling, timber bulkheads, or other conditions permitting the air to escape from the sill.

Direction of flow of air, and volume in cubic feet per minute.

The first numeral is an abbreviation of the number of the level, the letter indicates that the stopping is a door, and the last number is the number of the door in reference to the particular level. Bulkheads, and brattices, may be similarly denoted by a difference in the letter.

## Mine Fires and Hydraulic Filling

By H. J. Rahilly, Butte, Mont.

MINE fires, in the Butte District, have been a source of trouble and expense for the past thirty years. While the actual fire area in most of the mines has been comparatively small, the handling of the gas has generally been a much larger problem than the actual putting out of the fire. The chief causes of these fires have been: defective electrical equipment, incendiarism or carelessness, and spontaneous combustion.

Fires from the first two causes have been numerous, but generally they have been discovered and extinguished before they became serious. Spontaneous combustion has been the cause of most of the large fires. Sufficient heat has been generated by ground movement, high rock temperatures, and decomposition, to set fire to inflammable materials; tarred ropes, canvas, dry timber, manure and hay. Also, the heat resulting from the oxidation of the fine broken sulfide ore is sometimes sufficient to set fire to the timbers.

Digitized by Google

Prior to February, 1917, mine fires had been combatted by fighting the fire until it was extinguished or if, as so often happened, the fire was in inaccessible territory, the region was sealed and water introduced through diamond-drill holes put in from levels above. In that year, in fighting one large fire, it became apparent that any method of permanent sealing was going to be ineffective, because the ground was too badly broken and the use of water would be futile because it would form water courses in the stopes and would not spread out sufficiently to be of much value; therefore it was decided to fill this walled-off region with mill tailings. Prior to December, 1920. the tailing was taken direct from the Black Rock mill of the Butte & Superior Copper Co. Ltd., but when the mill was closed down, tailings were obtained by hydraulicking the tailing pond.

The following conclusions have been arrived at by the writer as to the operation and results of the filling:

1. This use of tailings will make possible the recovery of several million tons of ore in the Butte district.
2. It will extinguish the fire.
3. It will tend to eliminate high rock temperature.
4. It will eliminate gas.
5. It will help materially to increase ventilation.
6. It will tend to stop movement of the ground.
7. Material used is mill and flotation tailings consisting of 75 to 85 per cent. silica, and crushed so that 50 per cent. will pass 280-mesh screen. Little trouble is experienced in sluicing this material down a 3600-ft. flume on 2 per cent. grade, in 250 to 600 gal. of water per minute carrying from 20 to 50 per cent. of solids, by weight.
8. The wear on the pipe has been negligible; wrought-iron pipe for distribution laterals underground would serve better than cast-iron pipe, as it is cheaper and easier to handle, but the writer prefers cast-iron pipe in shafts and main distribution pipes.
9. Water drains through bulkheads and rock pillars, so that no great pressures are built up.
10. A rubber-lined pump has been tried at the tailings pond, but because of nails and small pieces of metal in the tailings, the rubber lining would not stand the service. Up to the present time, the use of this pump is still an experiment.
11. The success of the filling has depended on the use of fans, breathing apparatus, and the cement gun; without these the work would be difficult.
12. Filling of this character is particularly applicable to mine fires of large extent and long duration, where temperatures are high and the actual fire is inaccessible.
13. Under certain conditions, the filling might be used as ordinary mine filling, and to fill stopes that have been mined out, thereby excluding any possible chance of their catching fire.

## Power Distributing System for Deep Metal Mines

By C. D. Woodward, Butte, Mont.

THE Anaconda Copper Mining Co. purchases 25,000 kw. of electric power for its mining operations at Butte, Mont. This power is delivered over duplicate feeders in the form of 60-cycle, 2400-volt, three-phase current, to five compressor plants, where most of the energy is used for driving air compressors. At the compressor plants are located the switching apparatus for controlling the 2400-volt power and distributing it to the various mines. At these points, also, there are a number of motor-generator sets for converting the alternating current to 275-volt direct current for the haulage systems. Pole lines convey the power from the compressor plants to outdoor transformer substations at most of the mines. When it is not economical to distribute the power at the lower voltages in the mines, transformers and motor-generator sets are placed at strategic points underground.

All power is purchased on a maximum-demand basis, therefore there is installed at one of the compressor plants an eight-element totalizing graphic wattmeter. This instrument records simultaneously the value of all power taken at the numerous points of delivery, which not only eliminates the diversity factor but permits load dispatching between compressor and pumping plants, and thus materially reduces the maximum demand from the power system. Most of the mine hoisting is done by 90-lb. compressed-air winding engines, so that the air-compressor equipment for the winding engines and mining operations is quite extensive. Most of the compressors are directly connected to synchronous motors. The synchronous motors are designed for 80 per cent. leading power factor, thus facilitating power-factor correction of total mine load. By coöperation with the power company, the voltage of the power received at the compressor plants is constant.

In the mines, there are approximately 10,000 hp. induction motor and 4500 kw.-a. transformer capacity. It is the practice to install 2200-volt motors in the mines, except those rated below 50 hp.; there are in operation underground about 5000 hp., in the higher voltage motors, and approximately the same horsepower in motors wound for 440 volts. Approximately 50 per cent. of the motor load in the mines is required for pumping operations; the remainder is used for mine ventilation and haulage purposes.

In the early installations, lead or cotton braided armored cables were clamped by wooden cleats to the timbers of the mine shafts. A number of cable failures and fires resulted from this practice, therefore a number of improvements have been made. Cables installed in the pump compartments are always exposed and liable to an accident in the shaft. Where safety and reliability are required, electric cables should be put down through diamond-drill holes.

## Electric Haulage Systems in Butte Mines

By C. D. Woodward, Butte, Mont.

PRIOR to 1902, tramming ore from stopes to shafts, in Butte mines, was done by man or animal power. Demand for greater tonnage and the need for more improved methods of tramming resulted in the installation of compressed-air locomotives in a few mines. These locomotives were not generally adopted, because of a number of limiting features. They were superseded by electric trolley locomotives.

There are now operating in the Butte mines of the Anaconda Copper Mining Co., 185 trolley-type locomotives, each of which has replaced five animals.

The haulage conditions in this company's mines have many advantageous features that are not always found in underground mine workings. The drifts and crosscuts are large, approximately 5 ft. wide by 7½ ft. high, and have curves of no less than 18 ft. radius; and the roadbeds of the drifts and crosscuts have a uniform grade of 0.5 per cent. in favor of the loaded trips. In all of the mines, except two, the track gage is 18 in., and all tracks in the main haulageways are laid with 25-lb. rails. The average haul is 1500 ft., but a number of hauls are approximately 3000 ft. long.

Usually a train consists of ten loaded, roller-bearing cars. Each car weighs, when empty, 900 lb. and holds 14 cu. ft. of ore, which weighs about 1800 lb., thus the total weight of a train, without the locomotive, is 13½ tons. Normally, ten trips of ten cars of ore each are required per shift of 8 hr. on each mine level; this does not include, however, the tramming of waste or supplies. Waste is generally hauled during the time the ore haulage is light, as the material is usually trammed against the grade from the shaft to the stopes for back-fill. During a working day, the locomotives are in service 16 hr., hauling an average of 245 loaded cars, and returning the same number of empties.

A mine locomotive with a drawbar pull of 750 lb. would perform the work that has been outlined. To resist the abuse to which a mine locomotive is always subjected, larger equipment has been installed. The trolley locomotives now in service have a drawbar pull of 1450 lb., a speed of 5.3 mi. per hr.; and weigh 3½ tons. The trolley wire is carried in an inverted wooden trough placed at one side of the tracks and made of 2 by 8-in. strips for the back and 1 by 8-in. boards on each side.

As the trolley wire is a fire hazard and a potential danger to the workmen and as it limits the use of a trolley locomotive, particularly in the gathering operation, the storage-battery locomotive has been installed in a number of the Anaconda mines. The first storage-battery locomotive put into operation demonstrated that it was a success and, as a result, thirty additional machines were purchased, and most of them are in operation. The total weight of the locomotive is 4½ tons. It is rated at 1500-lb. drawbar pull at 3½ mi. per hr. on level track, with a maximum drawbar pull of 2500 lb. for starting and accelerating.

The cost of a trolley wire and track-bonding installation on the long hauls is about equal to a set of storage batteries for a locomotive, hence there is little difference in cost between a trolley locomotive and a storage-battery locomotive installation. The cost of maintenance of the two types of installation has been in favor of the latter, as the labor necessary to keep the trolley wire in alignment with the rails, due to the movement of ground in a number of the mines, and the constant repairing of the guard strip over the trolley wire, involves large expenditures.

There are now operating in the mines 22 storage-battery locomotives, hauling an average of 245 loaded cars and returning the same number of empties in a 16-hr. day.

---

## Electric Signal Installations in Butte Mines

By C. D. Woodward, Butte, Mont.

AT THE mines of the Anaconda Copper Mining Co., the movement of all mine cages or skips is under the direction of a station tender, who rides on the cages when men or supplies are being lowered or raised. When ore is hoisted, he is stationed at a skip pocket for loading and despatching the skips.

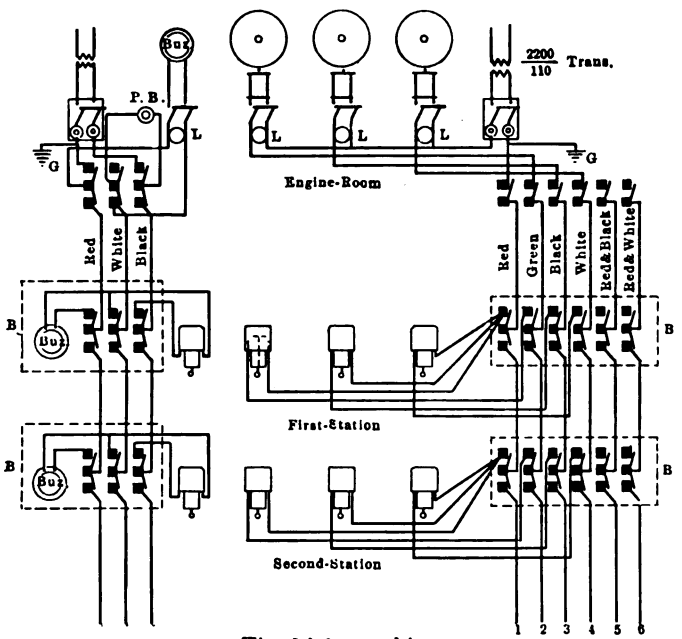
For the station tender's use, two signal systems are installed in each hoisting compartment, and he is the only employee authorized to use them. One system is known as the "AC" or station bells, as it is operated from the 110-volt, 60-cycle, power service; the other system, called the "DC" or shafts bells, takes its energy from closed-circuit primary batteries. As a supplement to the two main signals, a buzzer system is installed. The general arrangement is similar to the main signal, except that there is a mine buzzer at each station. When a signal switch connected into the buzzer system is pulled down, all buzzers are operated, thus notifying the station tender that he is wanted at some particular level.

Placed on the station posts, and within easy reach of the men on the cages, are the signal pull switches for the main signals. The station, or "AC," pull switches are furnished with a short rope, while the shaft, or "DC," pull switches are equipped with ropes that extend down the shaft past the next station. To avoid all confusion in the use of the three signal systems, a standard arrangement has been adopted in all mines for the location of the pull switches. The accompanying illustration shows the position of the pull switch at the stations for the main signal systems, but does not show the buzzer pull switch; this is fixed to the roof timbers about 25 ft. back from the shaft. If the skip pockets are a considerable distance below the station, a pull switch for each main shaft compartment is connected to the "AC" system and placed at this point. However, if the distance is short, a light cord

Digitized by Google

is attached to the station pull switches and dropped down to the skip pocket. To facilitate the sending of signals from any point in the shaft during the repairing or inspection period, the long rope hung from the "DC" pull switches at the stations is used.

On one side of the engineer's stand are three bells for the three sets of station pull switches; on the other side are three additional bells for the three sets of "DC" shaft pull switches. The bells have different tones so that the engineer can tell whether the signal is sent from either of the main shafts or the auxiliary shaft. In addition to these six bells, there is a buzzer operated by the buzzer signal system.



STANDARD ARRANGEMENT OF PULL SWITCHES.

In the "AC" system, each bell on the engineer's platform is connected in parallel with a lamp, and in series with a double-pole switch. If one of the signal wires or station pull switches becomes short circuited or grounded, thus causing the single stroke bell to be held up, it can be readily disconnected from the circuit. The lamp, however, will remain lighted and indicate when the trouble is removed. The buzzer system also has this arrangement, except that no lamp is used; but a push button is provided on the engineer's platform so that a return signal may be despatched to each station in the mine, which permits the engineer to call the station tender.

Starting from the engineer's platform, where the signal bells, lights and buzzer are located, three cables extend into the mine and terminate in junction boxes at the first station. From this point the cables are continued from station to station, passing through junction boxes. Each main signal cable contains six flexible No. 12, A.W.G. conductors, while the buzzer cable has three No. 8, A.W.G. flexible conductors.

The layout of the signal systems and the special apparatus described has been developed after considerable study to meet the service conditions in the Butte mines.

## Steam-shovel Operation by Phelps Dodge Corporation

By H. M. Ziesemer and George Mieyr, Bisbee, Ariz.

STEAM-SHOVEL operations may logically be considered under the following major subdivisions: breaking ground, shoveling, haulage, dump maintenance, and sampling. The discussion of methods and cost in this paper follows this outline, with a brief description of equipment used in the operation.

In breaking the material for rapid handling by the shovels, a combination of bank and toe holes is used to prepare the ground for the powder charge. The bank holes are put down by churn drills. The toe holes are put in with the Burley machines. The average footage per shift for the air drills, in all classes of ground, is 27 feet.

The arrangement of the holes on established benches of 60-ft. height is given. The toe holes are depended on to give the required bench advance at the toe and to maintain a level bench floor. The function of the bank holes is to slope the bank, lessen the burden on the toe holes, and to make the bank safe for the shovel to go under. A slope of 50° is considered desirable and is maintained as nearly as is practicable.

The following table gives the yearly average performance of churn drills, in feet per 8-hr. shift, and cost per foot:

| Year | Feet per Shift | Cost per Foot |
|---|---|---|
| 1918 | 12.5 | $1.74 |
| 1919 | 20.0 | 1.14 |
| 1920 | 24.2 | 0.94 |
| 1921 (9 mo.) | 31.2 | 0.55 |

Bank holes are sprung heavily to take a charge of from 300 to 800 lb. of powder, depending on the nature of the ground. Cordeau Bickford, an exploding fuse, is used as a detonator. The toe holes are sprung to take a charge of from 75 to 150 lb. of explosive and are loaded and fired in strings, the number of holes depending on conditions.

In general blasting operations, it may be said that distributing the powder uniformly through the ground would make finer breaking and would save delays in shoveling. However, the comparative cost of drilling and loading holes bored by churn drill or air drill must be balanced in deciding on a method of shooting.

The height of bank affects both methods of shooting and shovel results. A gelatine 40 per cent. powder, 1⅛ by 8-in. sticks, was used in springing holes and shooting boulders. Both nitro-starch and ammonium-nitrate powders have been used in bank and toe holes. The following figures give the powder efficiency, in

Digitized by Google

terms of solid yards per pound of powder used, and the cost per yard broken:

| Year | Solid Yards per Pound | Cost per Yard |
|---|---|---|
| 1918 | 1.43 | $0.158 |
| 1919 | 1.72 | 0.115 |
| 1920 | 1.97 | 0.100 |
| 1921 | 2.12 | 0.101 |

The operating crew consists of nine men: engineer, craneman, fireman, and six pitmen. The loading capacity of the shovels in favorable material has never been reached. The record 8-hr. shift is 124 cars, or about 2350 solid cubic yards. The following table gives the average yards per shovel shift, gallons of fuel oil per yard, and the cost per solid yard:

| | 1918 | 1919 | 1920 | 1921 |
|---|---|---|---|---|
| Solid yards per 8-hr. operating shift | 582 | 828 | 769 | 1038 |
| Gallons of fuel oil per solid yard | 0.81 | 0.65 | 0.60 | 0.56 |
| Cost per solid yard | $0.236 | $0.181 | $0.157 | $0.130 |

The broken material is separated into four products, as follows: direct smelting ore, milling ore, leaching ore, and waste. To date, waste has been the principal material handled, although small tonnages of direct smelting ore have been shipped to the smelters at Douglas, about 180,000 tons of milling ore have been placed in stock pending starting of the concentrator, and 375,000 tons of low-grade ore have been placed on the dump for heap leaching. In the earlier stages of the operation, it was necessary to locate waste dumps on adjacent hillsides.

The following table gives the cubic yards hauled per locomotive shift, the gallons of fuel oil used per yard, and the cost, including the maintenance of the dumps:

| | 1918 | 1919 | 1920 | 1921 |
|---|---|---|---|---|
| Solid yards per 8-hr. operating shift | 237 | 338 | 361 | 450 |
| Gallons fuel oil per solid yard | 1.45 | 0.95 | 1.03 | 0.87 |
| Cost per solid yard | $0.333 | $0.239 | $0.254 | $0.177 |

Seven shovels are regularly used for loading the broken material. They are all the Bucyrus Co. Model 88 C, which are standard machines designed for such work. They weigh 103 tons, are equipped with 3.5 yd. dippers and locomotive boilers. The maximum lift is about 75,000 lb.

Due to the hard ground and the high banks, considerable damage was done to the main frames, so all had to be reenforced over the front trucks. Also, the size of the A-frame legs was increased from 6 to 7 in. It is proposed in the future to equip all shovels with locomotive-type superheaters.

In starting a large shovel job, heavy costs are to be expected while building up an organization; in this case, the troubles were increased by the shape of the hill and the difficulties of getting the first benches removed. The following table gives the number of solid cubic yards moved per man-shift and the labor costs per yard:

| | 1918 | 1919 | 1920 | 1921 |
|---|---|---|---|---|
| Solid yards moved per man-shift | 7.84 | 11.74 | 12.02 | 15.28 |
| Cost per solid yard, labor | $0.590 | $0.387 | $0.419 | $0.312 |

The following table gives the average yearly cost per solid yard:

| | 1918 | 1919 | 1920 | 1921 |
|---|---|---|---|---|
| Breaking ground | $0.357 | $0.239 | $0.214 | $0.173 |
| Steam shovels | 0.236 | 0.181 | 0.157 | 0.130 |
| Haulage expense | 0.333 | 0.239 | 0.254 | 0.177 |
| Dump expense | 0.040 | 0.031 | 0.031 | 0.023 |
| Miscellaneous expense | 0.008 | 0.008 | 0.027 | 0.016 |
| Total | 0.974 | 0.698 | 0.683 | 0.519 |
| Monthly labor bonus | ..... | 0.004 | 0.023 | 0.029 |
| Total, Direct | 0.974 | 0.702 | 0.706 | 0.548 |

The improvements in costs and increase in efficiency are due both to improvement in the physical condition of the ground handled and the development of a good working organization. The paramount factor in an organization is efficient coöperation. The spirit of coöperation and the incentive to efficiency have been given the foremen, bosses, and men by the posting of graphic charts giving the daily cost and labor efficiencies in all departments. Another factor is the labor bonus based on the yardage per man shift whereby every employee benefits on a percentage basis.

---

## Handling Ore in Mines of Butte District

By H. R. Tunnell, Butte, Mont.

EVERY ONE connected with a mine knows that it is hard to keep down the costs of moving ore from the place where it is broken to the shaft or portal. Considered broadly, the subject of handling would cover all work done in a mine, but here it has been limited to handling ore in stopes and drifts, through chutes, and on levels. Good ventilation and a strict enforcement of rules for the prevention of dust safeguard the health of men and lower transportation costs.

About two-thirds of all the ore mined in Butte comes from square-set stopes. The shoveling and timbering costs in square-set stopes are high when compared with the costs in the rill stopes. The number of chutes is limited by the tendency of the ground to cave; if carried too close together the stope is weakened. Small stopes, or blocks as they are called, are used in working a large orebody, as they stand better and allow more of the ore to be handled on slides.

The rill stope is growing in favor throughout the district. These stopes are filled with waste from a chute at the upper end and floors are laid on this waste. The ore is drilled and blasted to the floor, which is from 40° to 45° to the horizontal, and runs to the grizzly at the lower end of the stope at a minimum cost for handling.

The timbered rill is a rill stope with square-set timbering; it is used where the vein is too wide and the back is considered unsafe for the open rill method.

The back-filling stope is worked without timber between chutes. The floors are level, as in the square-set stopes, yet rest on the waste filling as in the rills.

Digitized by Google

Except where the veins are very flat, under 50°, the back-filling stope has been supplanted by the open rill.

### Shoveling

Laying good floors and slides and careful sorting on the grizzlies are more important in a stope than using a shovel to put rock into the chute. Actual shoveling costs vary much for the different mines, as well as for individual stopes in any one mine.

Comparative shoveling costs for different methods of stoping are:

| | |
|---|---|
| Square-set stoping | 100 |
| Rill stoping | 75 |
| Timbered-rill stoping | 85 |
| Back-filling stoping | 120 |

The results show that the rill stope is most economical; the timbered-rill stope makes the application of the rill principle more general. The back-filling stope is used to meet special conditions. The square-set stope is still used in heavy ground and where large orebodies are to be worked in blocks. From 12 to 18 tons per man shift are shoveled in drifts and crosscuts. A No. 2 shovel with a straight handle 42 in. long is used throughout the district. Short shovels with a D-shaped handle were tried but were not liked by the miners. The tools used in shoveling are:

No. 2 square-point shovel, 42 in. handle
No. 2 round-point shovel, 42 in. handle
No. 4 picks
12 lb. rock hammers
No. 4 steel wheelbarrows
Anaconda type mine cars

Grizzlies are timber or steel rails spaced 4 to 10 inches.

### Handling Ore on Levels

Underground haulage is done by men, animals, or power. The amount of ore to be handled, length of haul, size of haulway that can be readily maintained, and the grades to be overcome determine which method is best adapted to any level.

Cars of the same type but of two sizes are used. The Anaconda No. 1, used in two mines, is 20-in. gage, holds 16 cu. ft., stands 3 ft. 10 in. above the rail and is 2 ft. 2 in. wide. The Anaconda No. 2, used in twenty-eight mines, is 18-in. gage, holds 14 cu. ft., stands 3 ft. 10 in. above the rail, and is 2 ft. 0 in. wide. These cars are small for motor haulage but, because of the heavy ground caused by settlement of stopes and sills in the wide orebodies, it has not been considered advisable to change to a larger car. Of the 7000 cars in use, 3000 have roller-bearing wheels, which will be the standard equipment.

For hand tramming, 12 to 16-lb. rails are used; for animal haulage, 12, 16 and 25-lb. rails, and for locomotive haulage, 25-lb. rails.

There are wide variations in the size and design of chute mouths at the different mines, the sizes run from 22 in. wide by 24 in. high to 36 in. wide by 20 in. high.

### Stations

The manner of handling ore trains on the stations is dependent on whether skips or cages are used to hoist the ore. If skips are used, the skip pockets are often large enough to store from 50 to 150 tons, although in some mines pockets holding one skipful are used and in others, on levels producing only a small tonnage, the cars are dumped directly into the skips. The cars from the trains are handled by station tenders (men working on cages) when the ore is hoisted by cage, dumped into the skip direct, and when pockets holding but one skip are used. With large skip pockets, the men on the train dump cars into the pockets; or if the tonnage is large enough a man is kept on the station to dump the cars. The cars are dumped through holes covered by a grizzly with opening not less than 10 in.; in some cases, as small an opening as 4 in. is used to sort out waste.

---

## Safety Practice for Hoisting Ropes

By R. M. Raymond, New York, N. Y.

THE Mining Section of the National Safety Council recently sent out a questionnaire to operators, regarding the class of rope used, specifications required or obtained, factors of safety observed, methods of fastening ropes, lubrication, inspection and points observed when rope is to be discarded. The answers received from this questionnaire, largely from metal mines, give interesting information, from which recommendations for safety practice on hoisting ropes may be drawn.

The depth in the majority of cases noted is from 1000 ft. to 1500 ft. and records come from a number hoisting from depths of 2000 to 3000 ft. Hoisting is generally done in balance, with a few companies using counterweights.

The range of loads varies from 7 to 17 tons and greater in a few cases, with a balanced weight of 4 to 7 tons.

The size of drums and size of sheaves are generally in accordance with recommendations of rope manufacturers. Only one-half of the operators use grooved drums; one, the Sulphide Corpn., New South Wales, uses wood-lagged drums. Very few operators have drums capable of holding all the rope in a single wrap. Cone drums or cone and cylinder drums, in the mines heard from, are very rare.

A few mines of shallow depth use a small drum and large-sized sheave. While this may be allowed, and in some cases is all right, the size of drum and sheave should be fully equal to that recommended by the rope manufacturers and should be at least 60 to 100 times the diameter of the rope used, or one thousand times the diameter of the largest wire in any of the strands.

Operations show two wraps wherever possible, and not more than three wraps on the drum; the choice of

Digitized by Google

several would be not more than one wrap if possible, and not more than two as good practice. A few operators, though too few, give importance to the distance at which the engine is set from the shaft and the fleet angle between sheave and drum.

The matter of overwind and underwind of ropes perhaps receives too little attention. The experience of operators in South Africa, according to Vaughan, of the Mines Department, indicates that the rope which underwinds wears more rapidly than the overwind rope by 20 per cent., and that the average life of rope is prolonged by alternating the ropes on the drums.

In a majority of cases, sheaves are cast iron, turned out true, 1/16 or 1/8 in. larger than the size of rope used. Others use special lining of cast iron, which is removable; the best type of this is the Nordberg sheave. Several companies use hardwood blocks, preferably maple. A few use hemp packing at first or to fill the groove when the sheave becomes worn. It would seem that more attention might be given to the material of sheaves and to the question of linings.

Ropes vary in size from 1 to 1½ in., generally 6 × 19, hemp center. A majority of the operators use the higher class rope, plow steel or special improved brands, and a few use a flattened strand, 6 × 25. A number prefer the Lang lay, which is the favorite with larger operators hoisting from the greater depths. Lang lay ropes are used in nine cases out of ten in South Africa; they are in very general use in Australia, and their use is becoming more general in this country.

Few companies stipulate specifications for rope; reliance is placed on the tensile strength given by the manufacturers. Preference is shown for plow steel by the larger operators, with the understanding that the tensile strength of the wires is, or approaches 200,000 lb. per sq. in. The International Nickel Co. calls for tenders from manufacturers, gives full description of working conditions, and asks manufacturers to recommend rope for these conditions, with complete description. It requires a factor of safety of seven for hoisting ore and a factor of safety of ten for the man hoist. The United Verde mine stipulates low-phosphorus steel, high carbon and manganese, with a tensile strength of the wires of 200,000 lb. per sq. in. The Copper Range Co. stipulates 1¼-in. plow steel, 6 × 19, regular lay; 58 tons tensile strength, and on test has found the rope to have a strength of 75 tons. The Broken Hill mine uses 1¼-in., 6 × 19, Lang lay and specifies a breaking stress of the rope of 60 tons and best flexible plow steel or its equivalent. The Anaconda company does not specify particularly, but uses improved plow steel in all cases

While the manufacturers' recommendations seem to be generally satisfactory, it is most important that purchasers give clearly their working conditions, nature of shaft lining, attention given to timbers and guides, the factor of safety desired, whether mine water is acid or not, and whether harmful gases are encountered in the lower part or any portion of the mine. The rope should be stored under cover, in a cool place, properly oiled and not left on the ground.

The Canadian mining law requires a certificate from the manufacturer showing date of manufacture, size, weight, number and size of wires, class of core, breaking stress of steel from which wire is made, and estimated breaking load of rope. This certificate is recorded in the "Rope Record Book" and additional data kept of operation of rope when in use at the mine.

CORRECT METHOD OF SOCKETING WIRE ROPE, GREAT BOULDER PROPRIETARY GOLD MINES.

The factor of safety stipulated or estimated varies considerably, generally that estimated by the manufacturers in supplying rope is considered satisfactory, and is five to six for new rope. Factors of safety for worn rope vary from three and one-half to five, and these variations for discarding rope correspond somewhat with speed and depth.

None of the state laws in this country indicate any factor of safety. The Canadian mining law stipulates a factor of safety of six in shafts less than 2000 ft. deep; and in shafts 2000 to 3000 ft., not less than five.

Digitized by Google

Speed in the shallow shafts submitted is from 600 to 1000 ft. per min. for ore, and in deeper shafts 1600 to 3000 ft. per min. Speed for hoisting men in almost all cases is reduced to 400 to 600 ft., though in a few cases it runs as high as 1000 ft. per min. Acceleration varies considerably, depending on depth. The accompanying table shows acceleration practiced by several of the important operators.

*Acceleration in Various Mines*

| | Shaft | Average Length of Haul, Feet | Maximum Hoisting Speed, Ft. per Min. | Acceleration, Ft. per Sec. per Sec. | Length to Reach Max. Speed, Feet | Time to Reach Max. Speed, Seconds |
|---|---|---|---|---|---|---|
| N. J. Zinc Co., Franklin, N. J. | Inclined | 915 | 3000 | 3.33 | 375 | 15 |
| Inter. Nickel Co., Creighton, Ont. | Inclined | 1600 | 1100 | 2.33 | 260 | 15 |
| Witherbee-Sherman, Mineville, N. Y. | Inclined | 1000 | 1200 | 1.33 | 150 | 15 |
| Copper Range Co., Painesdale, Mich. | Inclined | 1500 | 2360 | 2.48 | 130 | 10 |
| Republic Iron and Steel Co., Birmingham, Ala. | Inclined | 5400 | 2200 | 1.47 | 459 | 25 |
| Sulphide Corp., N. S. W., Australia | Vertical | 825 | 3650 | 5.06 | 300 | 15 |
| Calumet and Arizona, Warren, Ariz. | Vertical | 1500 | 1600 | 5.33 | 70 | 5 |
| United Verde Copper Co., Clarkdale, Ariz. | Vertical | 850 | 2000 | 4.7 | 115 | 10 |
| North Butte Co., Butte, Mont. | Vertical | 3600 | 2700 | 2.53 | 400 | 17 |
| Great Boulder Prop. Boulder, W. A. | Vertical | 2000 | 2000 | 5.85 | 95 | 6 |
| Old Ben Coal Corpn., Frankfort, Ill. | Vertical | 475 | 3600 | 12.00 | 150 | 5 |

Compared with the draft of the new mining law, the speeds for hoisting and accelerating speeds practiced by the different companies do not show any excess over the speeds recommended.

Method and frequency of inspection of ropes vary from daily inspection of terminals, including wraps remaining on drums, to weekly inspection. Fully 70 per cent. of the operators make inspection daily, and one makes inspection three times a day when hoisting men.

There is considerable diversity of practice in limiting the length of life of ropes. Several operators discard rope when the wires on the outside of the strands are worn to less than 60 per cent. of the original area, and when inspection shows signs of corrosion. Others take more particular note of the number of broken wires. One company discards rope when the number of broken wires in any consecutive 10 ft. exceeds 10 per cent. of the total wires in the rope; another very careful company condemns the rope when twelve wires per foot are found, or if the wires be pitted and can be pried out of place easily, even if no broken wires are found; another discards rope when 60 to 70 wires are broken in one strand. One company finds that a decrease of ¼ in. in diameter renders the rope unserviceable and cuts grooves in the sheaves; another company abandons the rope when a decrease of 3/16 in. in diameter is shown or when seven wires are broken in any one strand. The Anaconda Copper Co. discards when not more than 20 per cent. of the strength of the rope is used up by abrasion and broken wires. The Sulphide Corpn. generally discards its 6 × 7 rope when one wire in any way shows fractures; even if apparently in good condition, rope is discarded after two years service. One iron company turns the rope end for end every six months and discards it after a use of twelve months. The International Nickel Co., which takes special care of its ropes, abandons them after two years use, even if rope is apparently still in good condition.

## Wire Rope and Safety in Hoisting at Butte Mines

By W. N. Tanner and F. C. Jaccard, Butte, Mont.

THE wire-rope hoisting conditions at the mines of the Anaconda Copper Mining Co. in Butte, Mont., are very severe because of the conditions under which it is necessary to operate. A study was made, in the fall of 1919, for the purpose of changing these conditions in order to obtain longer rope and sheave life. There are at present, in Butte, hoisting engines equipped with wire rope as follows:

9 main hoists using flat ropes.
7 main hoists using 1½-in. rope.
5 main hoists using 1¼-in. rope.
6 shafts using 1⅛-in. rope.
2 chippy hoists using 1¼-in. rope.
9 chippy hoists using 1⅛-in. rope.
15 shafts using 1-in. rope.
7 shafts using ⅞-in. rope.
1 shaft using ¾-in. rope.

In addition, there are a number of sinking engines using ⅝-in., ¾-in., ⅞-in., and 1-in. rope.

The flat ropes run from ½ by 7½ in. to ⅜ by 4½ in. and are used on the older hoisting engines, which are set comparatively close to the shaft. Because of swelling and moving ground at some of the shafts, these ropes present certain difficulties in operation that are more pronounced than with round ropes; they are, therefore, being superseded by round ropes as newer engines are being installed. They are, however, much more easily inspected and repaired than round ropes.

In general, the practice in Butte is to use hoisting engines equipped with 12-ft. cast-iron drums, smooth faced, for 1½-in. rope and 6-ft. cast-iron drums, smooth faced, lagged with ⅜-in. steel plate for 1¼, 1⅛ and 1-in. rope on main and chippy shafts. Cast-iron head sheaves, 12, 10, and 6 ft. in diameter, with grooves machined 1/32-in. greater radius than the radius of rope, are used. Special steel ropes, either regular or Lang lay, according to conditions, are used; they are designed to withstand excessive abrasion and are wound on

Digitized by Google

drums in from two to four layers. The use of straight-faced drums has been general throughout the Butte district and is one of the conditions that tend to make rope service severe. On some hoists, the left rope is the overwind; on others, it is the underwind.

The head sheaves are so located that a line through the center line of the sheaves and parallel with the center line of hoist will strike the drum from ½-in. from the inner flange, as at the Pennsylvania hoist, to 15½-in. from the inner flange, as at the Neversweat hoist. The space between this line and the inner flange must be filled with rope at all times, for, if unwound in operation, this portion of the rope will not wind uniformly when hoisting the load. The sheaves are lined so that the centers of the grooves are in line with the center of the drums.

Considerable thought has been given lately to the subject of equipping the engines with grooved drums because of the easier rope conditions, to be obtained from these drums. Because of the lack of ground around some of the shafts, and other local conditions, the fleet angles vary from 1° 6′ to 1° 27′, for hoists having 6-ft. drums and 1¼-in. rope, and from 1° 12′ to 1° 53′ for hoists having 12-ft. drums and 1½-in. rope. The two main hoists with 6-ft. drums and 1⅛-in. rope have fleet angles of 1° 10′, 1° 24′.

The head sheaves are made of cast iron 6, 10, and 12 ft. in diameter, with the grooves machined to a radius 1/32 in. greater than the radius of the rope, and are carefully balanced to run perfectly true. Semisteel sheaves were tried but abandoned because it was impossible to get the material in the sheave uniform.

---

## Use of Wire Rope in Mining Operations

By James F. Howe, Worcester, Mass.

EVERY user of wire rope is desirous of information that will enable him to determine whether the performance of any particular piece of rope is satisfactory, and what conditions can be changed so as to increase the life of a rope. In most cases, it is far from easy to analyze the conditions of service and tell which is the greatest factor in determining the life of wire rope. If we start on a layout for an entirely new rope system, the task of making conditions satisfactory is simplified so far as the engineering details are concerned, but if the plant requiring wire rope is in operation, any change is likely to involve the expenditure of considerable money to replace and change over machinery that must be kept in constant operation, because a large monetary loss will result from a shutdown for even a few days. Often wire rope is kept operating under bad conditions, as the user figures that it is cheaper and quicker to replace the rope than to make alterations in the hoisting machinery.

Regular-lay and Lang-lay forms of rope construction are both old and both have their advocates. In Great Britain, Continental Europe, and South Africa, Lang-lay ropes constitute probably 80 per cent. of all used in mining. In the United States, probably 90 per cent. of all ropes in use are of regular lay.

In a Lang-lay rope, the wires in the strands and the strands in the rope are twisted in the same direction, giving the rope the characteristic appearance of being loosely twisted. Each individual wire appears on the surface of the strand for a longer distance than in the case of regular-lay rope. The worn spots on any wire are longer and such ropes appear to wear down farther than on a regular-lay rope. In a regular-lay rope, the wires in the strands have a left-hand lay and the strands in the rope have a right-hand lay. The rope has the appearance of being more closely twisted or laid together. A worn regular-lay rope exposes more worn crowns per foot but the worn spots are shorter.

If a Lang-lay rope is twisted in a direction to unlay the rope, the wires in the strands will untwist at about one-third the rate of the untwisting that occurs in the rope proper, assuming the same angle of lay for each. As a result of such untwisting, the outside wires of the strands are loosened, the amount depending on the amount of untwisting. Excessive stretching of a Lang-lay rope will produce about the same effect. The only opposition, therefore, to the continued untwisting of a Lang-lay rope is the stiffness of the individual wires to the torsional stress tending to untwist them. If a Lang-lay rope is twisted in a direction to shorten the lay of the rope, there is at the same time a shortening of the lay of the wires in the strands equal to about one-third of the shortening of rope lay. The result of this tighter twisting of the lay is to produce a double shortening of the rope; consequently, a powerful force is exerted against a shortening of the lay compared to a weak force opposing the untwisting action. For this reason, a swivel on a Lang-lay rope will often cause undue untwisting.

A force tending to untwist the regular-lay rope meets violent opposition because the wires in the strands tend to twist together by an amount equal to about one-third of the twisting of the rope, instead of untwisting as in the case of the Lang-lay. When the operation is reversed and a regular-lay rope is twisted together, the wires in the strands tend to loosen up.

Inasmuch as most wire ropes in service tend to lengthen in lay, or stretch, it is obvious that it is the behavior of Lang-lay and regular-lay ropes to the untwisting forces that is of most importance to rope users, as this is the action that occurs most frequently in actual service. The question, therefore, as to the adaptability of Lang-lay or regular-lay to any rope installation must be settled first on whether both ends of the rope are fast at all times. If they are, no harmful untwisting should occur that would deform the Lang-lay rope.

In the case of a shaft rope, safety demands that splicing must never be used; but on mine haulages, splicing

Digitized by Google

occurs frequently as worn sections are replaced by new ones. The lack of familiarity with the splicing of Lang-lay rope is one of the drawbacks to its more extensive use in the United States.

If a wire rope drags or rubs, as frequently occurs on an incline or haulage, then in general Lang-lay rope will give the best results. Also, in cases of severe overwinding on hoisting drums, the Lang-lay rope will frequently give the best service. One fact, however, must not be overlooked, foreign rope practice on Lang-lay rope application is to use the largest possible diameter of sheaves and drums, which of course has a decided effect on the whole problem.

The most common method of attaching a wire rope to a drum is to pass the end of the rope through a hole in the drum and either clamp it to the drum with U-bolts or clamps, or to pass the rope around the drum shaft inside the drum and fasten the end back on itself. At least three complete wraps are usually left on the drum when the cage is down to the lowest level of the lift. This method seldom gives trouble, but in a few cases there has been a slight creeping of the rope at the point where the rope goes through the drum as the load comes off with the cage resting on the bottom, causing wear at this point of the drum.

A better method, and one requiring less rope, would be to cast a zinc cone on the end of the rope after it has passed through the drum and have the drum recessed so as to receive the end of the rope thus treated; then no slippage can occur.

For fastening the end of the wire rope to the cage or skip, different methods are used. The ideal cage fastening should develop the full strength of the rope. Of what value is a high-grade rope designed to give a safety factor of 6 if the end fastening or attachment will give only 66 per cent. efficiency?

The various methods of making end fastenings on cages and skips may be classified as follows: wire rope clamps for forming small loop with thimble, wire rope clips for forming small loop with thimble, eye spliced in rope for forming small loop with thimble, and socket attachment.

A new method, the result of research work on the part of rope manufacturers seeking a more reliable method of socketing, is simple, cheap, and possesses the highest efficiency known to the rope art. It is rated at 100 per cent. The important points are to clean the wires thoroughly, to flux them with acid, and to use zinc, never babbitt or lead. Zinc adheres to the wires firmly; in fact, the wires are galvanized into a solid mass. This new method of socketing is fully described in Bulletin No. 75, U. S. Bureau of Mines, and is used exclusively by mines in South Africa for all their rope attachments.

The safety factor in a wire rope will be reduced by the following causes: (1) External wear; (2) breakage of individual wires; (3) corrosion by acid water, alkali water, electrolysis; (4) loss of elasticity; (5) fatigue in metal composing wires from regular or reverse bending, load variations caused by shocks due to starting and stopping or overloading, torsion at or near attachments.

## Safety Devices for Mine Shafts

By Rudolf Kudlich, Washington, D. C.

THE problem of eliminating the hazards of hoisting in mines has been with us since the industry passed its earliest stages, when coal and ore could be won from surface working and tunnels. At first, safety devices were introduced as means of decreasing the amount of labor necessary to produce the material, or to increase the amount that could be obtained from a certain opening. From such beginnings accident prevention in mine hoisting advanced with the importance of the industry, until at present hoisting compares favorably with other branches of the mining industry with reference to safe practices.

It is necessary to place our reliance mainly on mechanical devices to prevent accidents, and to depend as little as possible on laws, rules or other means involving the human element. This does not mean that we hope to install mechanical devices that will absolutely protect the workman against himself, or that it is possible to perfect appliances that will remain operative year after year without care; but better results can be expected from such devices, which will protect unless they are deliberately rendered inoperative, or are allowed to deteriorate to such an extent that they will not function.

To find where the greatest need of devices to prevent accidents exists, statistics should be studied to find how the accidents occur. Unfortunately, statistics covering accidents in metal mines are very incomplete so that our assumptions must be based entirely on the number and causes of accidents occurring in coal mines. These assumptions will not be far wrong for metal mines, as the methods employed are not radically different. The principal hazards, falling down the shafts or being struck by objects falling down the shaft, or while riding on cages, exist in both cases. Tables are given showing the number and kind of accidents and their causes for a period of 44 years.

The greatest number of shaft fatalities is due to falling down the shaft. Properly protected shafts, entirely enclosed by fence or gate are becoming common.

Of 1001 accidents, 145 were caused by objects falling down shafts. There are two methods of eliminating such accidents—preventing objects from falling and keeping men out of the danger zone. A few of the objects fall from the surface, where they are accidentally thrown or fall into the shaft; a few fall from timbers in the shaft, where they have lodged at some time; but the majority are pieces of coal or rock falling from the cars as they are being hoisted or dumped at the top.

Foreign objects can generally be prevented from

Digitized by Google

falling into the shaft at the surface, by suitable fences and toe boards, but those falling from timbers can be eliminated only by unfailing care on the part of the shaft repair men and inspectors.

The best remedy is to keep the men out of the danger zone at shaft landings; this is quite possible by the use of automatic caging devices. These devices are of benefit in so many ways that it is hard to understand why they are not more generally installed. From the safety standpoint, the automatic device eliminates entirely the need of men working directly at the shaft when hoisting coal. The empty cars are automatically released from the cage, when it is landed, and levers set at a distance from the shaft control stop blocks which, when released, allow the loaded car to run by gravity on the cage, where it is held by self-operating blocks.

The third largest class of hoisting accidents are those caused by overwinding. These can also be prevented by mechanical devices, though more complicated apparatus is required than in either of the preceding cases. This apparatus has the advantage, however, of being well protected from the weather and from dirt, and is under the direct care of the hoisting engineer, a man familiar with machinery and able to properly maintain it.

It may be questioned whether accidents occurring while sinking shaft should be included in shaft accident. This work is usually done by contract, and the methods employed are not usually under the control of the mine management; in many states, the work is not under the control of the mine inspector. I might say, however, that the principal offender is the crosshead, or billy. This is usually a simple wooden frame traveling between guides to steady the rope to prevent the bucket from swinging. As a rule, the crosshead simply rests on clamps on the rope, so that the rope is free to pass through the crosshead if the latter is kept from descending. Occasionally, the crosshead sticks, say on a lump of ice, or in a "tight place" in the guides, and its downward motion is arrested momentarily. After the rope and bucket have passed downward some distance, the crosshead may come loose, and falling may strike the rope clamp with sufficient force to break the rope or attachment. Several safety crossheads have been successfully used, which effectively prevent this accident. A catch is provided which automatically grips the rope and locks the crosshead and rope together, except when the former is resting on the stop-locks at the foot of the guides, and the grip on the rope is released.

It is only in anthracite mines, where coal is hoisted from several levels, and in metal mines where ore is hoisted in cars, that landing fans or keeps are used, so that this class of accident is rare. The cause is carelessness on the part of the foot tenders, who neglect to withdraw the keeps when going from an upper to a lower level, or of the engineer, who forgets to which level he is lowering the cage. The remedy is a signal system that indicates on the hoisting engineer's depth indicator, by light or some other means, just which keeps are in or out, showing the engineer at all times how far he can lower the cage.

To sum up the entire situation, we can safely say that almost all of the accidents commonly occurring in shaft hoisting can be avoided by the installation of suitable safety devices, and that with few exceptions such safety devices have been developed and can be used without interfering with the actual operation of hoisting in mine shafts.

## Sampling and Estimating Disseminated Copper Deposits

By Ira B. Joralemon, Warren, Ariz.

THE sampling of disseminated copper deposits has been described often but the method of combining assays to give the true shape and value of the orebody as it will be mined has received less attention. As the ore mined during five or ten years at several of the great disseminated properties has averaged materially lower in grade than the published estimates, the question of the sampling and estimating of these orebodies seems timely. In this paper, attention is given particularly to factors that may cause errors in the final estimate. Sampling of diamond-drill holes, churn-drill holes, and underground workings is briefly described in the first part of the paper. Then the method of combining assays to give the average grade and tonnage that will be mined is taken up in some detail. The necessity of study of the geology of the deposit and of probable costs is emphasized. Finally, the methods of calculating tonnages are outlined.

There are three main requisites for accurate diamond-drill sampling. First, the core should be removed and the hole cleaned out at the beginning of every sampling interval, usually 5 ft. Second, all sludge and core from every sampling interval should be saved. Third, core and sludge assays for every sampling interval should be combined in such proportion as to give the assay content of all material removed from the hole.

Churn drilling is somewhat less accurate, in most cases, than diamond drilling. Unless the hole is cased nearly to the bottom, the frequent passage up and down of the bit and bailer knocks off material from above the sample. If the values are in soft seams, the sample will be too high grade. Even if the ore minerals are disseminated through the rock, the sample will be affected by material from higher up in the hole.

The best sample from underground workings is made up of all the material removed after every round is shot.

Channel samples must be taken where existing underground workings must be sampled, or where it is not practicable to take a proportionate part of every round as it is mucked. The accuracy of this method depends on laying down a rigid system of sampling,

Digitized by Google

and adhering to it. The location and direction of channels should be most carefully studied, and the same channel interval should be used throughout the orebody.

Grab samples from rounds shot in underground workings are almost always high, and should be used only as rough checks on the other methods of sampling.

The results of all sampling should be recorded on assay maps, usually on a scale of from 50 to 20 ft. to the inch. Entering the assay, instead of the number of sample, on the map simplifies the later work of combining assays and estimating.

The ideal method for determining the assay content of a disseminated orebody is to check at least every fifth drill hole by a raise or test pit 50 or 100 ft. high or deep. One-tenth of all material removed from each round shot in these workings should be taken as a bulk sample, and the walls should be carefully channeled. As a further check, drifts should be driven between several test pits or raises, and bulk channel samples taken in them. By this combination method, the value of the deposit is absolutely proved, and the results of future drilling, raising, or test pitting can be trusted without further checking.

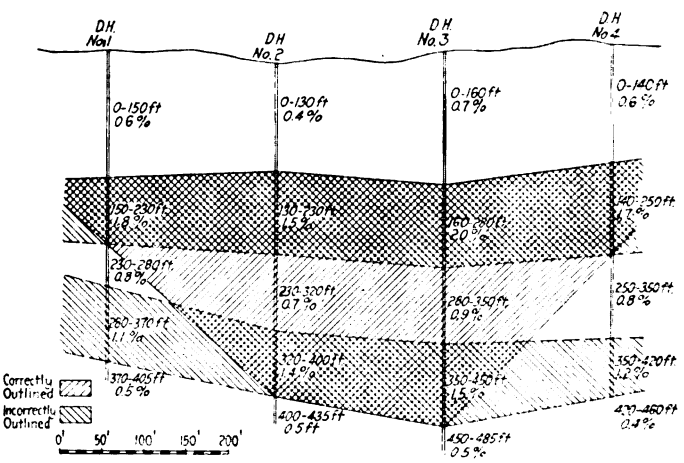
As an example of results of the three methods of sampling, in the development of the New Cornelia Copper Co., at Ajo, Ariz., over 1000 ft. of test pitting was done to check diamond drilling. The average of diamond-drill samples and of large channel samples checked to within 0.005 per cent. copper. The bulk samples, consisting of every tenth bucketful crushed and quartered mechanically, averaged 0.15 per cent. higher than the channel and drill samples. The drill and channel samples were accepted as correct. Several million tons of this ore have now been mined and treated. All of this ore to date has averaged 1.51 per cent. copper, compared with the estimate of 1.54 per cent. The grade has been a little higher than the estimate in one part of the orebody and lower in another part. This property has proved that, in a disseminated orebody it is possible to sample and estimate the ore correctly without reducing the grade by a factor of safety.

Before an estimate can be made that will check the mining, it is necessary to know what mining method will be used, and what the total cost of producing copper, and so the minimum grade of commercial ore, will be.

The tonnage, grade, and form of an orebody must be known in order to determine the mining system, costs, and minimum grade of ore that can be mined; and the mining system and minimum grade must be known in order to estimate the grade and tonnage of ore that will be mined. All the factors are interdependent.

The calculation of tonnage is a simple matter. Where the deposit is developed by drill holes on coördinates, the average depth of ore in holes on the four corners of every square, multiplied by the area of the square, gives a sufficiently close approximation to the volume of ore in the square block. The sum of the products of assay times depth of ore in the four holes divided by the sum of the depths of ore gives the average grade of ore in the block. If drill holes are not on coördinates, the deposit is usually divided into triangular vertical prisms, with a drill hole at every corner. The volume and grade of ore in every prism are found just as in the case of the square prisms described.

The sampling of a disseminated copper orebody is simple and should be very accurate. The estimation of tonnage and grade of ore in the deposit, once the length and grade of ore in every opening has been figured, is a simple mathematical problem. There is no excuse for great errors except where the irregularity of workings suggests the probability that richer portions of the orebody have been more thoroughly developed. The combination of individual assays in a drill hole or other opening to give the length and average grade of ore that will be mined is the difficult part of the problem of estimation. To solve it, the engineer must have an intimate knowledge of the geological occurrence of the ore, of the mining method to be used with its effect on recovery of tonnage and of copper, and of the total probable costs per ton of ore and per pound of copper, indicating the minimum grade of ore that will be treated at a profit. The failure to properly



VERTICAL SECTION THROUGH PART OF DISSEMINATED OREBODY SHOWING CORRECT AND INCORRECT OUTLINES OF ORE DEDUCED FROM DRILL HOLES.

study these factors is responsible for the fact that the ore mined in many disseminated copper properties has averaged from 0.1 to 0.4 per cent. copper lower than the estimates. This is an unnecessary error. The final estimate should check the tonnage mined almost exactly, and the grade of ore mined within less than 0.1 per cent. copper.

## Organization of Mine Sampling at Anaconda

By W. B. Daly and F. A. Linforth, Butte, Mont.

THE sampling and estimating of the orebodies in the mines of the Anaconda Copper Mining Co., at Butte, have been made a part of the work of the geologi-

Digitized by Google

cal department. The wisdom of this assignment is apparent, considering the organization of that department, the nature of its records, and the scope of its regular work. In the first place, the district is divided into units of two or three mines each and a geologist is assigned to each group. His trips to all the working places are frequent and he follows the mining operations closely. His notes are graphic and detailed. In the office, he posts his notes on the standard maps and sections and on special maps for correlation purposes. With the approval of the chief or assistant chief geologist, he recommends development work underground and watches its progress. This gives the geological department a precise knowledge of the character of each orebody.

Sampling is done by one or two samplers at each mine, working under a chief sampler stationed in the geological office. The chief sampler has access to all the office maps and is in frequent consultation with the geologists; his instructions to the samplers are issued with the approval of the chief or assistant chief geologist. Not only is it important that the geologic information be used to direct the sampling, but the reports of the samplers and the records kept by their chief are useful to the geologist, who needs them in his work of estimating ore reserves and deciding on recommendations for development work. The sampler, moreover, is at the mine every day and makes a daily report, which keeps the geologist in close touch with the progress of development work. The sampler is attached to the mine office and thus comes under the jurisdiction of the operating department.

The ore deposits to be sampled are veins varying in width from a few inches to 50 or 60 ft. Steep dips predominate although dips at all angles are found. The veins belong to a complex system of fissuring of different ages and present a wide variety of vein filling. Some exposures present a hard mineralization of fairly uniform character from wall to wall, but many contain bands of altered granite, crushed in the process of faulting and carrying only scattered particles of metallic sulfides. A large part of the orebodies consist of veinlets of chalcocite or enargite traversing granite in such close succession as to make valuable ore of certain masses. Throughout the district, however, the structural features are fairly well defined and have served as a guide to the sampling.

The first step under the present organization was to classify all the probable occurrences to be sampled into a few standard types. Four types were found to be enough, to cover all exposures in the faces of drifts; they are: uniform ore; part good and part low grade; part good, part low grade, and part waste; narrow streak good but balance doubtful.

The sampler is required to examine each place to be sampled and decide to which type it belongs. He then takes the required number of samples, at breast height, along a horizontal line, irrespective of the dip of the vein. He also measures the width horizontally. This measurement is correct because the longitudinal sections upon which the ore blocks are laid out are projections on vertical planes. The ideal cut, or channel, across the face of the drift is impractical, from an operating point of view. Too much time would be lost if the miners had to wait while the sampler laid out and chiseled a neat groove across the vein; indeed, the varying degree of hardness of parts of the vein would make such procedure difficult. The same results are accomplished by the use of the sampler's pick. The sampler takes equal amounts of material from points along a predetermined line and catches it in a sack held open by a wire ring. Tests show that the accuracy of such sampling is sufficient for operating purposes.

For the estimating of ore reserves, there is a longitudinal section of each vein made to a scale of 1 in. = 100 ft. and projected on a vertical plane parallel to the strike of the vein. A certain minimum width and assay value is assigned by the operating department as the lower limit for ore. The drifts and raises on the long section are colored red wherever the assay curve shows the required grade of copper ore, and green for zinc. Waste drifts and raises are colored gray. This color scheme shows quite plainly what should be included in the ore reserve for each section. Blocks are laid out, therefore, upon the section and their volume and tonnage calculated in the usual way. For the grade of these blocks properly weighted, averages are calculated either from the curve records or from the more complete daily reports in the ledgers.

## Sampling and Estimating Zinc and Lead Orebodies in Wisconsin

By W. F. Boericke, Chicago, Ill.

UNLIKE western vein deposits, the Wisconsin orebodies do not lie between regular walls, but form large, often highly irregular bodies, on a single floor in the so-called Galena limestone. The bottom of the ore is nearly always on a flat generally well-defined clay seam, a few inches thick, which marks the junction of the base of the Galena lime and the top of the next formation, the Trenton lime. Above the clay bed, the orebodies make the unique pitch and flat formation described by Chamberlain. Theoretically, we should find two pitches, one on either side of the top crevice, diverging as they go down, with the final flats a considerable distance apart on the clay bed. The area between, known locally as core ground, should thus constitute a single defined orebody, with the richer portions near the pitches and the leaner portion in the center of the core. Practically, we find few examples of this perfect orebody. Almost invariably one pitch is

Digitized by Google

better defined than the other, and often the opposite pitch is marked only by a faint line of fracture showing stronger mineralization than the wall rock, or it may be totally lacking.

Late mining developments in the rich New Diggings field indicate that these pitches often assume a horseshoe or crescent shape, the richer ore being in the heart of the crescent, and the pitches showing less mineralization as they extend outwards. The length of the orebody may be several thousand feet, the height varying from 10 to 60 ft. and the width from 60 to 250 ft. In fact, on the core side, there is no definite end to the ore. The mineralization simply gets thinner and thinner, and the limit of working depends on the cost sheet and the profit from the recovery.

The mines are worked almost universally with underhand (breast) stoping, using a room-and-pillar method for carrying the ground. In most cases, a drift is is carried along the edge of the ore in advance of the stopes, and new stopes are opened up on the pitch as needed. These open stopes are frequently of great extent, sometimes 40 to 80 ft. high and 40 ft. wide between pillars.

Obviously it is impossible to sample such a stope by the usual methods, on account of the rapid changes in the richness of the pitches. Long practice and experience in the field, however, enable the mine operators to make surprisingly good estimates of their ground and the probable mill recovery, from visual examination alone; and by drawing proper amounts of dirt from the different stopes, a generally consistent mill feed is obtained.

Mill recovery, in itself, gives only an approximate idea of the ore in the ground. With free milling ores, the recovery may be good, and with chatty ores the recovery may be poor, from ground showing originally the same mineral content. Yet in the absence of elaborate and costly sampling of the mill feed and tailings, slimes, and overflow waters, the mill recovery serves as a rule of thumb to determine the mineral content of the ground, and is so regarded by the operators. I do not know of a case where an effort was made to sample the ground by underground methods alone. Reliance is always placed on visual examination of the ore faces, supplemented by known mill recoveries.

Churn-drill holes, spotted in advance of the heading or stope, give the most reliable method of sampling or estimating these orebodies. This is an expensive way to get the information and is only used when it is necessary to drill out additional ore, or to prospect with the idea of acquiring new leases or new ground for mining. In most cases the drilling precedes the actual development and mining of the orebody, so that from a careful record and study of the drill logs, a tolerably good idea is gained of the mineral content of the ground, the height of stopes, direction and dip of pitches, character of the back, etc.

When it is determined to drill ahead of an existing stope, a drill is spotted according to a careful survey about 50 to 100 ft. ahead of the stope, along the general direction of the range. Knowing the respective elevation of the surface and the back of the stope, the drill man is instructed to cut runs down to 2 or 3 ft. when he reaches the depth where he should get the top of the ore. All sludgings, thereafter, are carefully sampled and saved for subsequent examination and assay by the drill engineer in charge of the work. The drilling is continued until the clay bed, or glass rock, the next formation, is reached, regardless of whether the ore continues down or not. The drill engineer makes a log of the hole, for office use, noting particularly the character of the ground, with any change of formation, the amount of zinc, lead, and marcasite (known locally as sulfur), the presence of open ground and crevices, the water level, and particularly whether the ore occurs as sheet, disseminated, or crevice ore and any other items of interest that may help to interpret the hole.

In brief, this is the ordinary procedure in estimating the orebodies in Wisconsin. In general, the results, as shown by subsequent mining and milling practice, have been reliable, but there are many cases of disappointment. This has been often due to the failure to recognize the character of the ore (that it is not free milling) or of the ground, especially in disseminated deposits. Either condition may give higher assays than will be shown in subsequent development. It pays to be reasonably conservative in reporting on drill holes, and invariably to disregard rich runs and assays if they do not indicate a consistent mineralization of the ground, as checked out by other holes. Beware of orebodies with "freak" drill holes.

---

## Stope Cost Records and Mine Contracts of the Anaconda Copper Mining Co.

By C. L. Berrien, Butte, Mont.

BEFORE the present company was formed, in 1916, each group of mines comprising the old organizations made its detailed daily and monthly mine cost records along the lines used before the consolidation; that is, there was no attempt made to standardize and compare the stope costs of all mines. The general cost sheets for all mines, however, were standardized, and cumulative labor cost sheets were compiled in the general superintendent's office.

Probably 95 per cent. of the stopes were square-set worked by day's pay; there were some back-filling and shrinkage stopes. Many of the development places, such as shaft sinking, station cutting, drifting and raises had always been run by contract. These contracts were given, for no definite period, at so much per linear foot and were measured monthly, or when completed, the men being paid monthly. In some cases, fairness to the employee was not maintained. On the whole, there was no standardization. There were no stope contracts, because of the objections of

Digitized by Google

the Western Federation of Miners to general contracting in the mines.

Early in 1916, W. B. Daly, then general superintendent, and the author, then assistant general superintendent, visited the southwest mining districts with the object of finding some improved method. On account of local conditions on the surface, as well as underground, the fact was kept in mind that no new method would be acceptable that would cause:

1. A settling of the surface or any underground workings or shafts then in use, or that would be used in the future.
2. A lowering of the grade of the ore.
3. A violation of the rules of the Safety First department.

The result of this trip was the adoption of the following methods:

1. The cut and fill, or rill system, in all veins where the ore and walls are fairly hard, whether the ore must be sorted or not.
2. The timbered rill, where the ore and walls are not hard, whether the ore must be sorted or not.
3. The use of chutes every fifth set in square-set stopes and the more general use of slides to chutes.
4. The keeping of daily cumulative detailed costs for each stope that the foreman may check the efficiency of his men.
5. The employment at each mine of men having a thorough knowledge of underground mining and accounting to maintain a system of detailed costs.

## Record Forms

In connection with these new methods, it was our desire to provide for obtaining, recording and using the following information:

1. The comparative efficiency of different stoping methods.
2. The comparative cost of labor by different stoping methods.
3. The comparative cost of supplies by different stoping methods.
4. Total saving by new methods over old.
5. Efficiency, labor and supply costs of each stope in each mine and the separate details of these costs.
6. Periodical cumulative costs of all stopes.
7. A record of all mines stope costs for each foreman and superintendent.

Each mine, at the end of the month, has a completed stope cost record, which is sent to the office of the general superintendent, where the general stope cost record for all mines is made up. This sheet is almost a duplication of the mine stope cost record. It is made on tracing cloth, blue printed, and sent to each foreman and assistant superintendent. Powder, caps, and fuse are combined under explosives and net savings of the other methods over square-set stoping are shown. This system, and the methods of obtaining the information, have been used five years and have required no changes.

The custom of contracting on sills, in shafts, raises, and stations still is carried on; repair work, stoping, tramming and all other work had always been by day's pay. Stope contracting, though, was not practiced until April, 1919. This system was gradually installed until, by July 1, 1919, it was an actual working success in all stopes at all mines. Work in all stopes, raises, drifts, crosscuts, shafts and winzes is now done by contract on a cubic foot basis, the price per cubic foot being regulated according to conditions, such as the hardness of the ore or waste, the width of the ore, the method of stoping, accessibility, temperature, and humidity.

## Benefits of Contracts

The contracts are made for one week, at a set price, but may be terminated after one day by either the foreman or the contractors. The men are notified of the price on Thursday morning, which is the beginning of each contract week. No change in the rate per foot is permitted during the life of the contract, but adjustments are made in special cases, which must be noted by both the engineer and the foreman. The general benefits derived are:

1. The cost per ton of ore is less by contract. The men who are willing to work are given some individuality and the conservative men are inclined to break away from the I.W.W. theory of doing as little as possible in order to get by.
2. The stope cost record and contract system have given a more accurate check on the cost of underground operations than any method we have used.
3. By subtracting the ore tally from the engineers' contract measurements, a direct check on waste broken or tons of rock broken to obtain a ton of ore in each stope is obtained.
4. Measurement is allowed between the walls only, except where the wall is removed for timber. It is, therefore, to the best interests of the men not to break the walls, and the ore is kept cleaner and the average grade increased.
5. By taking the difference between the total labor cost of a stope on the stope cost record and the total contract money, the direct percentage of contracting in each stope or at each mine is obtained. Over 90 per cent. of the stope shifts are contract shifts. Any comparative cost data desired may be obtained directly from these records.
6. The contract system tends to keep the foremen and all bosses in closer touch with the mine and creates better supervision. When contracts are given, the list is posted at the mine showing price per foot and, when finished, full information of the results is posted, showing: contract number, working place, price per foot, total shifts, total money, and rate earned. Every man at the mine is paid weekly, which accounts for a great part of the successful operation of contracts.

It is understood at all mines that any contractor is free to interview the foreman of the mine and, if a satisfactory adjustment of his complaint is not made, he may take his case to the company labor commissioner. The case is then brought to the general superintendent. During the period of general contracting from April, 1919, to date, over 60,000 contracts have been let, but only six have been brought to the general superintendent for adjustment. This record is sufficient evidence that the method is a proper one, and can only be attained by the most careful superintendence and absolute fairness to the employees.

# Some Considerations Affecting Percentage of Extraction in Bituminous Coal Mines in America

By H. H. Stoek, Urbana, Ill.

A STUDY of American coal-mine practice shows two of its distinctive features to be: A greater number of accidents per thousand employees than in any of the other leading coal-producing countries; a much greater percentage of the coal is lost than is the case in any of the other leading coal-producing countries. Although our subject is mainly concerned with the second feature, any consideration of mining methods should include safety, efficiency, and economy.

If in defense of our wasteful mining the argument could be offered that it was necessary on account of safety, and that it is carried out with less loss of life than is the case in other countries, the plea for conservation of coal could not be so strongly urged; but when we are wasteful of both life and property, the subject merits more consideration than it has received.

Space will not permit a detailed discussion, but a study of the literature on better coal recovery and a field study of successful methods will confirm the following conclusions and suggestions:

1. In considering the applicability of a method of extraction all of the conditions must be considered. For instance, the concentration method of the H. C. Frick Coke Co. used in many parts of the Connellsville district, where the geological conditions are similar to those of Illinois in most respects, is carried on under operating conditions that are quite different from those that prevail in most of the Middle West coal fields. An essential consideration for high recovery is a mobile labor force, which premits concentration of miners, and a rapid removal of the coal is necessary for the most successful recovery by any concentration method.

2. While there is a similarity in the successful methods used for obtaining high percentages of recovery, no standard and universal method has been developed; there are, however, a number of methods that adapt the same general principles to a wide variation of local conditions.

3. The best results are obtained by companies that mine under a definite projection plan for the future and are not dependent on immediate financial returns. The best result will undoubtedly be obtained by driving entries to the boundries of the coal area and drawing the pillars full retreating. Very good results are being obtained by drawing pillars within panels by driving the panel entries to the limit of the panel, then beginning the rooms at the inbye end of the entry so that pillar drawing may begin as soon as the inbye room is finished.

4. The successful methods for obtaining a high recovery get most of the coal from the pillars and not from the rooms, as in ordinary room-and-pillar work. The development of the present practice has been by a gradual widening of the pillars sometimes accompanied by a decrease in room width, but not always. Where best results are now being obtained rooms from 12 to 20 ft. wide are driven upon 90 to 100-ft. centers, thus leaving a pillar from 80 to 88 ft. wide. The width of room seems to depend more on whether or not yardage must be paid rather than on the nature of the roof.

5. For successful pillar work, strain on the roof above the rooms must not be great enough to cause the roof to fall before the pillar coal is removed or to make the cost of timbering such a roof prohibitive. The fall of roof in the rooms may be overcome by making narrow rooms, but the very narrow rooms used in some districts do not seem to be necessary.

6. A fundamental principle in pillar work, to prevent squeezing the coal back of the working face, is to take out as nearly as possible all of the coal so as to secure a roof fall as near as possible to the face of the pillar. Great care is taken not to leave stumps of coal in the gob, even though the coal recovered may not pay for the work of removing the stump, or may have to be abandoned in the gob, as they retard roof breaks.

7. It has been found wise, generally, to protect the men driving through pillars by a narrow curtain pillar between the working place and the fallen gob, this curtain pillar being removed in great part as the track is taken up in the working place.

8. Subsidence of the surface should be considered a probable accompaniment of pillar drawing and the pillars should be removed systematically so that the resulting subsidence may occur uniformly and not in isolated spots, for, although there may be a temporary disturbance of the surface with systematic pillar drawing, the surface conditions after a short time may be as good as or nearly as good as before the pillar drawing.

9. If the mine is at all gaseous, permissible explosives and electric safety lamps only should be used in the pillar work, as the men necessarily work near the old gobs where falls are constantly occurring.

10. Although statistics are not available regarding the relative numbers of accidents in pillar drawing and room work, a number of inspectors connected with liability-insurance companies and operating officials have expressed the opinion that there are no more accidents in pillar work than in ordinary room-and-entry work and that, while such work requires careful workmen, often they are not unusually skilled.

11. Pillar coal does not necessarily mean more fine coal, as is generally assumed, although care must be taken to prevent the making of fines. The increased use of fine coal will remove one of the great obstacles to pillar drawing; *viz.*, the fear that the percentage of slack will be increased.

12. The interpretation of the mine law in West Virginia regarding the spacing of crosscuts as meaning 80 ft. apart between openings on opposite sides of the room and not on the same side, as the laws are commonly interpreted in other states, has permitted

Digitized by Google

a staggering of crosscuts and locating them 160 ft. apart on each side, thus giving a better condition for pillar drawing.

13. It was formerly considered that pillar coal must be hand mined but in recent years, particularly with the large pillars now used in many regions, the use of machines has proved practicable.

14. Undoubtedly one of the great drawbacks to more extensive experimentation in pillar drawing has been the fear of the operator in union districts that any improvement may mean a lengthy controversy, possibly a strike, and most surely a demand for an increase in the mining rate which may make a prohibitive differential against the proposed method.

15. It has been suggested that the government might set up a regulation requiring certain methods to be used that would give a maximum production under existing conditions, but this has not been tried and most likely it will not be except possibly in connection with some of the federal leases in western lands.

---

## Mining Methods at the Ashio Copper Mine

By Masayuki Otagawa, Tokyo, Japan

THE mining methods adopted in Japanese mines are less known to the mining world than those of other countries, owing to the geographical remoteness, but they present many features of interest to mining engineers.

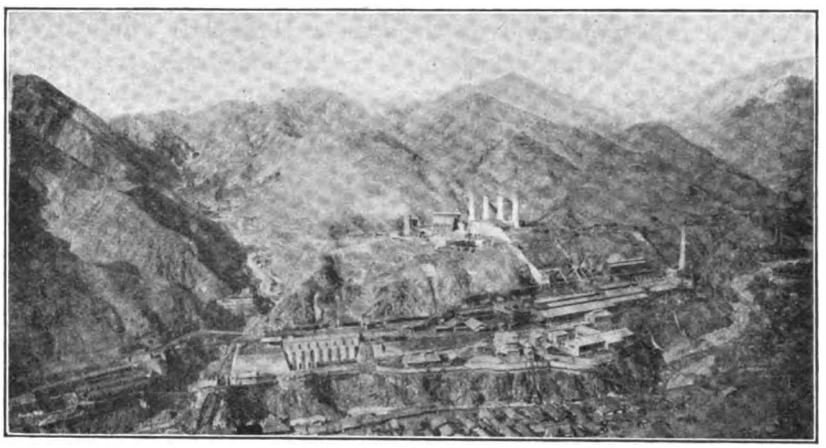
The Ashio copper mine is at the village of Ashio, in Tochigiken, about 109 mi. from Tokyo by railroad. The area of the concession owned by the Furukawa Mining Co. is 5000 acres. The mine was formerly divided into three, *viz.*, Honzan, Kotaki, and Tsudo, which are distant 3 mi. from each other. In 1914, when the writer was general manager, the three mining plants were amalgamated into one with the result of simplifying the working projects and increasing the operating efficiency.

The mine was visited by the Institute party in November, 1911.

Since the discovery of the enormous masses, called "Kajika" or "Bullhead" deposits, described by the writer in Mining and Metallurgy of December, 1920, the mining methods have been varied to meet the different conditions presented by these deposits.

The country rock of this mine consists of slate and quartzite into which has been intruded a plagioliparite neck more than 2 mi. in diameter, in the shape of an inverted cone which narrows downward to a relatively small diameter in depth. Nearly all of the deposits are veins, and they occur for the most part in the liparite, although a few are found in the sedimentaries.

The mine is developed by adit levels and blind shafts and is at present being worked to the depth of 3500 ft. below the surface. The daily output is 1000 tons o



General view of Ashio Smelter.

copper ore, mined from veins and kajikas in nearly equal amount.

Overhand stoping is employed in the veins. Each stope is 6 ft. high, 10 to 15 ft. long and more than 2½ ft. wide, depending on the thickness of the vein. The system of mining the kajikas is mostly by open, stepped-face, square sets. Development drifts are in either wall of the deposit with raises to the level above, and the sill floor is breasted out from the drift to each wall. The room is supported by round square-set timbering, 6 ft. square, center to center, both cap-wise and girt-wise and 6 ft. high. The sill floors are 7 ft. high. The diameter of the timbers for post, cap, and girt is 10 in.; on the main sill, 12 in. Since the ground is firm enough, the sets alone are relied upon to support the walls without filling. The ore is drawn off through inclined chutes into cars on each level and trammed to the shaft station. In most cases, cages are used in the shafts, but a skip with 2.5 tons capacity is installed in the Yokomabu shaft No. 2, which has a depth of 1080 ft. Kajika deposits are too wide for stulls, and the ground is fairly strong, but requires prompt support to prevent slabs falling from the back and walls; so this method of mining is justified by the lower cost of exploitation.

Although there are still many mines worked by the square-set system in the United States, in spite of the growing preference for shrinkage, filling and caving systems, there are few mines in Japan where the conditions are suited to the square-set method.

The Ashio mine was the first one where machine drills were extensively employed in Japan. Among them, Leyner Ingersoll, Ingersoll stoper, Jackhamer, and Ashio drills are chiefly used at present, the latter being designed and manufactured by the engineers of the mine. Its construction is much like that of the Jackhamer, having a butterfly valve, but it is much simpler and weighs only one quarter as much.

# Can Anthracite Mines be Operated Profitably on More than One Shift?

By Dever C. Ashmead, Kingston, Pa.

FROM time to time metal-mine engineers have inquired why anthracite mines and their preparators are rarely operated on the two or three-shift basis. The subject may be approached as affecting: labor, development, the underground workers, the preparator, the outside workers, capital, the supply account, power consumption, the storage of coal over various shifts, railroad car supply, and the market.

From the start, the adoption of a plan of three full-shift operations in a day would cause difficulty with the colliery employees, for they have never worked on that plan and would show their resentment by suspending work. Even if they could be induced to work according to this schedule they would not be as efficient.

Operation on a three-shift basis would necessitate triple manning of each working place, and dissensions would arise betwen the men, for each shift would claim that the preceding shift had taken undue advantage and had not left as favorable conditions as they had found. To obviate these disputes it might be necessary to let out the work to a contractor, who would hire his helpers to mine out the chamber, or breast. The state mining law requires that a miner be put in charge of each working place. To conform with this provision he would have to hire three helpers and two miners to mine the breast. The labor unions have been trying to abolish the subcontractor in mine work and any method of working that would cause his return, however innocent in purpose, would result in labor disturbances.

It might be possible to form partnerships of three miners working a place together, but the men would probably have frequent dissensions as to the proportion of work performed by each shift. Only one other method of working remains—operation by company men—but this is ordinarily too expensive to be considered.

In addition, the state mining law requires that before he can become a miner a man shall have two years' experience and then pass an examination. This limits the number of miners available, and if all of the anthracite collieries were to go on a three-shift basis there would not be enough men to fill the working places.

The development work in those parts of the mine in which there is first mining is often on the three-shift basis. It is only with difficulty that this development work is kept sufficiently far in advance of the coal-mining forces to keep them supplied with working faces.

Ordinarily, with three shifts a somewhat greater number of foremen would have to be engaged. Where, of course, there is but one opening the number of foremen must be increased for there must be one man in charge of each shift; but where there is more than one opening there is usually a foreman for each.

If the mine were placed on three shifts, the number of men would have to be increased somewhat, for men would have to work on the ventilation in every shift, so that promptness in making repairs would be assured. More door boys would be required.

It is, however, in the solution of the transportation problems incident to the triple shift that the biggest difficulty would be encountered. The three-shift operation might well involve an increase of 150 per cent. in the transportation force without any compensation derivable from larger tonnage. The trouble today is that sections of the transportation system cannot be worked to capacity, therefore any dilution of the traffic by the introduction of the three-shift system would merely intensify a condition that even now is sufficiently crippling.

In those mines where silting is practiced, the three-shift plan would make it necessary to silt on all three shifts, provided that the preparation equipment as well as the mine was run with equal continuity. This would mean increasing the force almost 200 per cent. and yet obtain only the same output and do the same amount of silting.

In order to show the effect of the output on the number of men employed, nineteen curves have been compiled from data from ninety collieries having an annual output of 44,205,896 tons. The data from each colliery are plotted separately and an average made for each 50,000 tons increase; these points are indicated by a circle. The curves give due weight to these sub-averages, considering the number of observations involved in each. The high or low points apparently neglected are usually from meager, often single, observations or from known abnormal conditions. The curves are intended to represent general conditions, not individual cases.

The conditions under which triple shifting might be arranged have been tabulated, noting in each case the results favorable or unfavorable, deviating from the time honored plan of single shifting mine and preparator.

*Assumption* 1.—A mine of normal production operating under present methods.

*Assumption* 2.—An old mine with the preparator in good condition and operated with first and second mining; it is desired to place the mine on full three-shift operation to triple the output.

*Assumption* 3.—An old mine that can be operated by dividing the present force into three parts, each part working an integral portion of the mine, and operating the preparator on a three-shift basis. (*a*) By working different beds in different shifts; (*b*) by working different shafts, slopes, or drifts in different shifts.

*Assumption* 4.—The whole mine worked on a one-shift basis and the preparator on a three-shift basis.

*Assumption* 5.—A new mine, a preparator to be so planned as to operate on three shifts.

*Assumption* 6.—A new mine to be laid out to operate on three shifts and the preparator on one shift. (*a*) The output to be the same as operating under

Digitized by Google

present methods; (*b*) the output to the maximum for each shift.

*Assumption* 7.—A new mine to be designed to operate on one shift and a new preparator on three shifts.

*Assumption* 8.—A consolidation of two or three collieries each to be operated on a separate shift, and the preparator to be operated on a three-shift basis.

*Assumption* 9.—A consolidation of two or three collieries each to be operated on three shifts and the preparator on a single shift.

*Assumption* 10.—A consolidation of two or three collieries, all to be operated on the same shift and the preparator on three shifts.

*Assumption* 11.—Two of three collieries to be abandoned and work to be concentrated in one colliery producing the same tonnage as obtained from the three; both colliery and preparator to be operated on three shifts.

The ten main conditions that must be considered in the multiple shifting of anthracite collieries are shown above and in Table 4; besides these others might arise in the case of any particular colliery.

There may be individual cases where multiple shifting of anthracite mines might be advisable due to peculiar conditions that are not general throughout the fields. It might be advisable, in case of accident to one operation, to give employment and maintain output, or if for any cause there is a serious shortage of coal, or on account of the pending expiration of a lease on a property. Such an operation would not be multiple shifted for any saving in operating expenses or continous use of capital but on account of special conditions.

Double shifting instead of triple has not been mentioned but the conditions and the items affecting this would be similar but less in degree.

From a study of the preceding, the effect of the different assumptions on the operation is shown and it appears that not one of the assumptions shows as economical and practicable a method of operation as the usual—a mine that operates on one shift and preparator of which also operates on the same shift.

---

## Non-metallic Mineral-filler Industry

By W. M. Weigel, Tuscaloosa, Ala.

IN THIS paper, and generally in the trade, the term *mineral filler* is applied to a mineral used in its natural state after mechanical preparation only (such as grinding, milling and washing), without undergoing any chemical change and without exerting any chemical action on the substance with which it is incorporated.

The consumption of mineral fillers is confined chiefly to large manufacturing centers in the eastern and northern states.

The common mineral fillers are white clay, barite, mica, talc, whiting, ocher, silica, graphite and slate. The methods of mining and preparation, which are quite different, are discussed separately.

Sedimentary or transported white clays are the only clays used to any extent as fillers; the residual white clays, or kaolins, go to the ceramic industry. The principal centers of the clay-mining industry in the southern district are in the vicinity of Langley, S. C., and in the central part of western Georgia. Clay is used as a filler in the manufacture of paper, rubber, oilcloth, paint and, to some extent, in phonograph records, polishes, textiles, matches, and soap.

Barite is produced in Georgia, Tennessee, North Carolina, and Alabama; Georgia ranking first and Tennessee second in production. Deposits of sufficient concentration to justify mining consist of fragments of all sizes from sand to pieces weighing several hundred pounds, mixed with clay, pieces of rotten limestone, and sometimes quartzite. Barite as a filler is used in paper putty, textiles, and phonograph records, but mostly in the paint and rubber industries. For paint and paper, fine grinding and pure white color are demanded.

Graphite occurs chiefly in Clay, Coosa, and Chilton Counties, Ala.; this state which, since 1915, has produced over 60 per cent. of the domestic graphite, has been the subject of numerous papers and reports. The uses of graphite as a filler are rather limited, largely because of its flaky structure, its color, its electrical conductivity, the difficulty of grinding it to a fine powder and of obtaining a product free from grit. The highest grade graphite, free from grit, is used as a filler in lubricants; the lower grades, containing 60 to 75 per cent. carbon, are used in paint, stove polish, and foundry facings.

Mica, due to its characteristic structure, is a valuable filler in some lines of manufacture. North Carolina is the largest producer, but considerable mining is also done in Georgia and Alabama. Wet-ground mica is used largely in the manufacture of wallpaper, as a dressing or dusting powder for high grade rubber goods, such as casings and tubes, and in the compounding of rubber. This is one of the highest priced fillers. The superiority of water-ground mica is said to be due to its better luster, its ability to stay longer in suspension in water, and its lightness or low apparent specific gravity. Dry-ground mica is used as a coating on ready roofing, in some lubricants, phonograph records, ornamental paints, dusting or dressing powder for rubber, pressed, and molded goods and artificial stone.

The talc industry of the south is most extensive in southwestern North Carolina and northwestern Georgia. Ground talc is used as a filler in paper, paint, textiles, shoe polish, toilet powder, soap, artificial stone and to some extent in rubber, oilcloth and other articles. It is used largely as a dressing or dusting powder for rubber and roofing, leather, cordage and other lines of manufactured goods; the cheaper off-color grades are used as

Digitized by Google

foundry facing, alone or mixed with graphite. Paint and paper require white talc; for toilet powder only the extra white is used, very little of which is produced in the south.

Whiting, the common name for finely ground marble or limestone, is one of the most widely used fillers. True whiting is ground chalk; other ground calcareous materials are substitutes. Production is now confined to Georgia, Tennessee, and North Carolina. Both dry- and the wet-ground are used in rubber, paint, a few grades of paper, linoleum, oilcloth, shoe polish, putty, tooth powder, roofing, artificial stone and asphalt paving.

Most of the southern ocher is produced near Cartersville, in northwestern Georgia, though promising undeveloped deposits occur in other states. Considerable amounts of red oxide of iron are produced, but this is generally used for its color and not as an inert filler. Domestic ocher is used largely as a filler in linoleum and to some extent in paint. While its color falls below the standard of some of the French varieties, recent tests indicate that the oil absorption of Georgia ocher is somewhat lower. It is used to a limited extent as a filler in some grades of rubber and paper.

Silica that may be used as a filler occurs as diatomaceous earth, quartz, and tripoli. Diatomaceous earth has been mined in Florida. Tripoli, which has resulted from the weathering of chert or siliceous limestones, has commonly been produced in preference to quartz as a silica filler on account of the ease of grinding. Silica as a fine-grained filler is used in paint and wood filler, in metal polishes, nearly all scouring soaps and cleansing powders, and to some extent in phonograph records and rubber.

Ground slate, or slate flour, is a comparatively new filler material. As a rule, it is ground from the scrap resulting from quarrying and working slate used for other purposes. Recently, however, the increased use of slate-surfaced roofing and shingles has created a demand for crushed slate, or so-called granules, that has been met by operating slate quarries especially for this purpose. Deposits of slate that are worthless as roofing slates or other products requiring sound material are suitable for granules if the color satisfies the roofers' demands. Red and green slates are used most widely, though dark gray is used to some extent. Slate granules are now produced in Georgia and Tennessee.

The technology of mineral fillers is for the most part an undeveloped field. Few of the filler producers have carried on any research work with a view to improving the grade of their products or adapting them to wider uses. The larger consumers have recently begun to realize the importance of careful laboratory tests of fillers, for such tests indicate why certain fillers are best suited to their needs. It is safe to say that no two consumers, even in the same lines of manufacture, have the same specifications for their fillers. Study, experimentation, and publicity will result in a better knowledge of the physical properties of fillers and will point the way to their more scientific preparation and use.

## Effect of Quality of Steel on Case-carburizing Results

By H. W. McQuaid and E. W. Ehn, Canton, Ohio

IT IS usually assumed that chemical specifications are sufficient for steel to be used for case carburizing and if the steel analyzes within the ordinary limits specified for steel for this purpose, no difficulty traceable to the steel used should be encountered in obtaining satisfactory results in the case carburizing and hardening. Much work has been done to determine the effect of various alloying elements on the rate of carbon penetration, etc. but, little has been published in regard to the effect of the quality of the steel on the final results in the hardening of case-carburized steel parts.

The writers believe that the structure of the case both before and after quenching is greatly affected by the actual condition of the steel itself as made, and that for good results in the case-carburizing and hardening departments, the steel should be of the best possible quality as regards non-metallic impurities.

It is the purpose of this paper to prove that the presence of excess dissolved oxides in the steel, as made in the melting furnace, affects permanently the results obtained in carburizing and hardening and that it is possible that the presence of dissolved oxide can result in total unfitness of low-carbon steel for case-hardening purposes.

In the work discussed, in spite of the most careful inspection, trouble would occasionally develop in the hardening of case-carburized material, and large quantities of material would be rejected after hardening because soft spots were found by the file. This, it was noted, occurred in particular lots of work when nearly 100 per cent. of the pieces showed soft spots in the hard inspection test. The pieces, it was also noted, could be traced almost exclusively to certain heats of steel made in basic open-hearth furnaces.

When it was found that large quantities of certain sizes would not harden properly, the first step taken was to recarburize for a short time. This, in nearly every instance, failed to improve the result of the hardening. When it was found that the work that resisted all attempts to harden was confined to certain lots of basic open-hearth steel, checks were instituted to determine the cause of the difficulty.

Microscopic examination of many specimens of carburized work developed a striking difference between steels that would show soft areas after quenching and those that would be satisfactory. By a careful comparison of carburized steel from bars known to produce poor results with steel that gave good results, it

Digitized by Google

became possible to determine, after carburizing, whether or not the pieces would have soft areas after quenching. It also became evident that, for some reason, a characteristic structure in the hypereutectoid zone was formed after carburizing in the steel giving trouble, which made it almost impossible to retain the normal martensite after quenching.

Microscopically, it became a simple matter to detect steel, after carburizing, that would not form normal martensite after the quenching, the difference between it and the normal steels being easily distinguished by the experienced observer.

It was found that the results to be obtained in carburizing and hardening varied with different heats of steel as made. This seemed to offer a means of checking and eliminating this class of steel as a steel of carburizing quality, because it was only necessary to carburize a section of a small test ingot poured from the ladle. This test was finally adopted after carefully checking. It was found that if this small test ingot, poured from the middle of the heat, was unsatisfactory, apparently the whole heat was unsatisfactory.

In order to determine the fundamental cause of the condition that affected the carburizing results, many experiments were made. The fact that in an otherwise normal steel, a ghost line through the case after carburizing would cause the pearlite to break down, with a very abnormal structure at this point, would indicate that the segregation of sonims in the ghost lines was a contributing cause.

## Electrolytic Deposition of Iron for Building up Worn or Undersized Parts

By David R. Kellogg, East Pittsburgh, Pa.

THE electrodeposition of iron has been practiced for many years. During the war, the British army repair shops developed a method for building up worn parts of automotive machinery, aero engines, etc., using the cold sulfate bath and low-current density method. The method has been used successfully in commercial work for the production of about 6000 repaired parts. Experiments along the same lines have since been made at the Westinghouse research laboratory.

As a result of preliminary work, the procedure recommended by Thomas was adopted. After the piece had been cleaned with gasoline or benzine, it was made the cathode in an alkaline bath containing about 5 per cent. commercial lye and about the same amount of sodium carbonate, the exact amount being immaterial. A current density of 3 to 5 amp. per sq. in. was used. The piece was treated in this bath for 3 min., then it was washed in running city water and made the anode with approximately the same current density in 20 to 30 per cent. commercial sulfuric acid for an equal length of time.

This process gave smooth, tough, adherent coats which, when deposited on a carefully ground rod 0.485 in. in diameter and then ground to a thickness of 0.001 in. could be pressed through a hole in 1-in. cold-rolled steel 0.0005 in. smaller than the finished size of the rod, and then pressed back again with no signs of stripping.

A motor shaft having bearings $\frac{5}{8}$ in. in diameter by $1\frac{1}{2}$ in. long was purposely finished 0.002 in. small in diameter, plated oversize, reground to proper dimensions, and then assembled and run in bronze bearings for 1000 hr. with a load of 50 lb. per sq. in. projected area, using a short stiff belt with a clipper joint in order to give a pounding effect as well as friction. At the end of the run it was found that the wear was 0.0002 in., which is just a trifle less than the original material shows in factory-life tests. Plug and thread gages have been repaired by this means and have given good satisfaction although they are not as hard as heat-treated tool steel.

Some work of N. B. Pilling, as yet unpublished, has shown that the brittleness due to occluded hydrogen may be completely removed by heating for $\frac{1}{2}$ hr. at 300° to 400° C.

When cast iron is put through the electrolytic cleaning process, it emerges from the acid with a coating of graphite. It was thought that it would be useless to attempt to plate anything so covered with slime, but a cast-iron rod cleaned in the usual manner, covered with graphite and placed in the plating bath, was coated with entire success. Carefully ground test rods of cast iron were plated with a coating which, after grinding to 0.376 in., left 0.001 in. of coating and others were left after grinding with 0.010 in. of coating on a side. These were pressed through a hole in 1-in. cold rolled steel that was 0.0005 in. smaller than the finished size of the test piece, then pressed back again, but showed no tendency to chip or strip off. While it is usually cheaper to scrap standard cast-iron parts accidentally machined undersize, there are many cases where replacement of special parts would mean making new patterns and then casting, in which case the time and expense saved would amply pay for the necessary work of reclamation.

---

## Crystal Structure of Solid Solutions

By Edgar C. Bain, Cleveland, Ohio

IT SEEMS likely that one of the new avenues of approach to many metallographic problems is the study of crystal structure, or, more accurately, the atomic arrangement, by means of the X-ray spectrometer.

The crystal structure of some materials has been carefully worked out by the mineralogist, but his methods, in general, are unsuited to commercial metals and a method that yields even better information is at

Digitized by Google

hand as the result of work on the diffraction of X-rays by Laue and the Bragge, and later by Hull, St. John, and others. It should be understood that the contour of free crystals, which is the subject of measurements by the crystallographer, is the result of the atomic structure and, in general, bears a simple and obvious relation to it. The use of the X-ray spectrometer has been described frequently.

### Essential Characteristics for Each Metal

All metals are normally crystalline. Crystallinity requires regularity in atomic spacing; hence, parallel planes of regular spacing can be passed in many ways through a crystal grain containing all the atom centers. The distances between such planes are the data recorded photographically by the X-ray spectrometer. These planes act as a three-dimensional grating for diffraction; the nature of the assortment of such interplanar distances found in a crystal determines its type. The ultimate measure of these plane spacings is merely the distance along a strip of photographic film where darkened lines appear exactly as they appear on a photograph of the spectrum of visible light, for instance. Of course, instead of having a constant grating and analyzing the wave length, we have a constant wave length and measure the grating.

The logical first step in applying such study to metals is the determination of the atomic arrangement or crystal structure for all the useful pure metals. Both the type and the dimensions of the space lattice for the atoms in metals are computed from the pattern of lines on the spectrogram. Hence, this photographic pattern is essentially characteristic for each metal. A number of such photographic films are shown. So far as is known, the pattern for any metal differs at least in dimensions from the pattern of any other material.

In eutectics studied by the author, there were cases of limited solubility in the solid. But the two patterns revealed on the film were substantially identical with the two pure-metal patterns. Thus, the tin-lead eutectic showed both the pattern of lead and the pattern of tin, while in fact there were no crystal-grains of pure lead present but a solid solution of a small amount of tin in lead. Silicon-aluminum eutectic showed exactly the same evidence, though aluminum dissolves over 1 per cent. of silicon. This led to the prediction that a solid solution has a crystal structure similar to the structure of the solvent.

### Summary

1. A solid solution forms by replacement of solvent atoms by solvent atoms. If the pure solute is of a different crystal type from the solvent, the parent lattice changes very little in dimensions. In such cases, a limit of solubility is reached and at this point a new lattice is formed which may be an intermediate or the lattice of the solute.

2. Intermediate lattices, based on weak compounds probably, are present in the complex series.

3. When two metals, alike in crystallographic type, form continuous solid solutions there may be a gradual change in lattice size from one pure metal to the other.

4. Other supposed continuous isomorphous series are actually composed, for some range, of two separate crystalline phases. Both forms are likely in the same grain.

5. Thermal treatment may shift the range of overlapping lattices toward one or the other pure metal. The effect is most noticeable if one of the pair of metals is allotrophic.

6. For some constitutions of perfectly annealed solutions, the location of the solute atoms is probably known.

7. No case was observed where solid solution occurs by new atoms filling in the interatomic spaces (if such spaces exist), and it is not predicted that such cases will be found.

---

## Spectrum Analysis in an Industrial Laboratory

By W. H. Bassett and C. H. Davis, Waterbury, Conn.

THE ease and value of the application of spectrum analysis to industrial chemistry appears to be appreciated in few of the large works laboratories of this country. For eight years, this analysis has been of great value to the authors in both analytical and metallurgical work.

To the analyst the complete qualitative analysis of an unknown alloy, revealed by a spectrogram, is a sure basis for the planning of the most direct and rapid method of attack. As the determination of each element proceeds, the purity of precipitates may be checked as often as desired.

The spectrograph proves invaluable in the recognition of impurities, the separation of which would entail a lengthy and difficult procedure, or when the weight of an unknown is less than is necessary to complete the desired determinations. A few hundredths of a gram will usually suffice for spectrographic analysis.

In the separation of the rarer elements, the spectrograph will show, with precision, the point where each step has been successful. In zinc of certain classes, indium, gallium, and germanium have been isolated in this way; the presence of antimony in lake coppers has been proved; and bismuth has been detected in zinc and in alloys where the presence of a few thousandths of a per cent. would be harmful. An antimony precipitate in a delicate determination may contain a considerable proportion of tin or arsenic, both of which will be revealed. The spectrograph is consequently important to the metallurgist as well as to the analyst.

Impurities in raw material are often a source of annoyance, especially when their detection involves delay and costly analytical work. Whether low con-

Digitized by Google

ductivity in copper is due to arsenic, nickel, or something else may be quickly found out. Residual traces of boron, magnesium, manganese, silicon, vanadium, and other deoxidizing agents are easily identified where wet analysis may fail to reveal their presence, even after days of effort. Complex alloys of any kind are dissociated by the spectrograph into a spectrum, the reading of which gives the elements present, together with an idea of the relative amounts of each. The secrets of the inventors of alloys and hardened metals are no great problems when, for their solution, one can depend on the application of the microscope and spectrograph.

In plates accompanying the full paper, several spectrograms are given showing the dispersion and quality of the lines and instances of the general usefulness of the large quartz spectrograph.

This article is the summary of a few instances where spectrum analysis has proved its value and is intended to show the ease, accuracy, and rapidity of accomplishment in one field only—that of metallurgy.

## Experiments with Sherardizing

By Leon McCulloch, East Pittsburgh, Pa.

WHEN clean iron and metallic zinc dust, protected from the air, are heated below the melting point of zinc, the iron takes on a coating that has excellent protective value. This coating is a brittle alloy of zinc and iron, and the process is called *sherardizing*. Although the zinc particles are covered with oxide and cannot touch the iron, an extremely small amount of the zinc vaporizes and the vapor, reaching the iron, alloys with it. Other zinc then vaporizes to replace that which has been removed from the atmosphere. This process continues indefinitely at a decreasing rate, for the coating already formed permits zinc to diffuse through it to combine with the iron beneath. In this way, the coating grows outward from the surface of the iron, as the bark grows from a tree.

The composition of sherardized coatings varies from the outer surface inward, as would be expected from the mode of growth. That is, the iron content increases slowly at first, then more rapidly as the iron is approached. At the surface the least amount of iron possible is 6 per cent. as the experiments described in this paper have shown.

A study was made of the effect of iron in zinc dust on the process and on the resulting coatings. From the curve between iron in the dusts and iron in the resulting alloys, certain conclusions can be drawn:

It is evident that no part of a sherardized coating can contain less than 6 per cent. iron, as heating even for 45 days fails to lower the amount at all. When the dust contains less than 6 per cent. iron, the resulting alloy contains 6 per cent. As the iron is increased from 6 to about 10 per cent. the composition of the alloy changes proportionally.

These results are in general accord with the well-known equilibrium diagram for the zinc-iron alloys. There is this material difference, however, these results show iron to be insoluble in zinc at temperatures below the melting point, while the diagram indicates a solid solution containing about 1 per cent. iron.

The iron content in a dust should be low, but there is some question as to what the limits should be. "Dross" dust containing iron is cheap and the percentage of iron increases with use, as zinc is removed while the iron remains. Iron in dust is useful as it raises the melting point and prevents fusing or caking when a high temperature is used to give rapid deposition. Iron, however, rapidly lowers the rate of deposition, making it necessary to employ higher temperatures.

The iron content should not exceed 7 per cent. An analysis of the dust should include the metallic iron. The important thing is the ratio of the metallic iron to the metallic zinc, rather than the percentage of iron to the total dust.

Life tests show that there is a minimum weight of zinc per square inch necessary for good coatings. To test the value of sherardizing, the weight of zinc should therefore be determined. There are various proposed methods for doing this. A new method depends on the fact that a boiling 10 per cent. solution of ammonium chloride removes zinc from sherardized coatings rapidly, but does not dissolve iron until the zinc is practically gone. This test may be applied in two ways: The coating is completely removed and its amount determined by loss in weight; or the weight of the coating is found approximately by noting the time for iron to appear in the boiling solution. At each 5-min. interval, a drop of the solution is removed upon a spot-plate and tested with potassium ferricyanide for the presence of iron. When the blue color appears, the coating is gone, and the time is a measure of the weight of zinc. A good coating should withstand this test for 10 or 15 minutes.

## Arsenical Bearing Metals

By Harold J. Roast and Charles F. Pascoe, Montreal, Que.

THE object of this investigation was to compare the arsenical antimony lead alloy with some of the regular bearing-metal alloys. With this end in view, the following tests were made:

1. Chemical analyses to show the composition.
2. Thermal analyses.
3. Macroscopic examination of fractures.
4. Microscopic examination.
5. Tensile tests.
6. Crushing tests.
7. Scleroscope tests.
8. Brinell tests, at temperatures from 80° to 400° F.

Tests 3 to 8 were conducted on both sand-cast and chill-cast specimens.

For the purposes of this paper the alloys have been numbered from 1 to 6; their composition is as follows:

Digitized by Google

| Number | Lead, Per Cent. | Antimony, Per Cent. | Tin, Per Cent. | Copper, Per Cent. | Arsenic, Per Cent. |
|---|---|---|---|---|---|
| 1 | 82.64 | 12.95 | 4.40 | 0.01 | none |
| 2 | 27.54 | 9.94 | 59.87 | 2.65 | none |
| 3 | 77.65 | 20.75 | none | 0.13 | 1.47 |
| 4 | 82.95 | 16.85 | none | 0.20 | none |
| 5 | 83.78 | 15.35 | none | 0.05 | 0.82 |
| 6 | 0.15 | 7.87 | 84.13 | 7.85 | none |

The analysis, in the case of the antimony, was made by solution in sulfuric acid and titration with permanganate. For tin, the ferric-chloride method was used; for copper, the alkaline separations, and the thiocyanate methods; for arsenic, volatilization of arsenic and titration with iodine. The lead, with the exception of alloy, was taken by difference.

With the exception of No. 5, the alloys were taken as received from the manufacturer. About 40 lb. were melted in a graphite crucible and recast into small ingots to ensure uniformity of composition; samples for analysis were taken from these remelted ingots.

Of the six alloys taken for comparison, the high tin base is undoubtedly the hardest, the strongest, and the most resistant to crushing loads. On the other hand, all the alloys stand 1000 lb. per sq. in. without deforming, and all deform but slightly at 5000 lb.; in other words, none would be expected to squeeze out of a bearing at ordinary loads. Leaving out No. 6, the arsenical alloys maintain their hardness as the temperature rises better than the other alloys. Structurally, the arsenical alloys have by far the finest grain while having hard crystals embedded in a softer but tough matrix. The arsenical alloys can be poured at a lower temperature than No. 6 and run more readily at, say, 700° F. than any of the other alloys. Further, they show less sign of oxidation. In the matter of cost of components, the arsenical alloys (not taking into account the special cost of alloying in the case of the latter) will be less than the high tin alloys but more than alloys 1 and 4. All of these tests have been carried out from the practical rather than the academic point of view and several lines of experimental work are suggested.

## Studies on the Constitution of Binary Zinc-base Alloys

By W. M. Peirce, Palmerton, Pa.

THE present work has been done in an endeavor to correlate and complete the data on the constitution of alloys of zinc with other common metals, dealing exclusively, however, with the zinc-rich alloys in which the zinc content is between 90 and 100 per cent. This investigation has included the systems lead-zinc, cadmium-zinc, iron-zinc, copper-zinc, aluminium-zinc, nickel-zinc, manganese-zinc, cobalt-zinc, tin-zinc, and magnesium-zinc. The important ternary system zinc-lead-cadmium and the zinc corners of other ternary systems have been investigated in connection with this work but are not treated in this paper.

Zinc does not form a single homogeneous zinc-rich solid solution over any considerable range of concentration with any of the metals mentioned. A limited range of solid solubility is said, by previous investigators, to occur in several cases and certain effects on the properties of zinc are attributed (with varying degrees of consistency among different writers) to the presence of certain other metals dissolved in zinc. The increasing use of rolled zinc and the possibilities offered by zinc as a casting alloy in certain fields have made it essential to determine precisely these equilibrium relationships.

In carrying out this investigation, reliance was placed chiefly on two methods, conductivity measurements and microscopic analysis. The first method proved valuable in determining the existence and extent of solid solubility. The second method stands alone as a means of determining structural characteristics and supplements the first method in the measurement of solid solubility. No hardness curves are included in this paper, for in no case were they important in arriving at the constitution of any system.

It is impossible in a brief abstract to enumerate or describe the 51 diagrams illustrating the results of these valuable researches, all of which are given in detail.

## A Possible Origin of Oil

By Colin C. Rae, Denver, Colo.

THE absence of paraffin hydrocarbons in the soil, although they are concentrated in extensive deposits in some localities, the common distribution of plant remains through many formations that are not productive for oil, and many other factors, seem to indicate the existence of an intermediate organic compound between the complex plant compounds and the paraffin hydrocarbons; and much evidence points to the humus acids or associated organic compounds, which are probably collected by surface waters and concentrated in certain areas by means of precipitation by electrolytes, which would be contained in sea water or possibly in various inland seas or lakes.

There are many present-day evidences of the association of petroleum with humus acids. Many of the rivers carry much humus acid in solution, and some tropical rivers carry in the aggregate millions of tons of humus each year. The analyses of various river waters show a close relationship between the amount of organic matter and the amount of free uncombined silica. By chemically equating the positive ions to the negative ions in the various analyses of river waters, there is apparently an excess of free silica, most probably in a colloidal state, varying from a fraction of 1 per cent., in rivers with little organic content, to 44 per cent. in tropical rivers, such as the Uruguay.

Digitized by Google

The relation between the silica and humus is not clearly understood and prominent chemists have given conflicting views concerning the physical and chemical relationship.

The combined silica is chiefly in the form of sodium metasilicate, which has been shown, by Kohlrausch and others, to be hydrolyzed in solution into colloidal silica and sodium hydroxide. Uncombined silica must be present as colloidal silica since silicic acid hydrolyzes, forming the colloidal solution. A colloidal suspension is finely divided solid matter in the presence of the solvent.

Another factor to be considered is the possible precipitation of organic compounds by sea or inland lake waters. Binney, Haseman, and others have called attention to the association of formation of petroleum or asphalt with humus conditions in the presence of sea water. Chemically, the coagulation of colloids is effected by electrolytes such as $Al_2(SO_4)_3$, $Fe_2(SO_4)_3$, $FeCl_3$ and other salts, when present in sufficient quantity. When sufficient electrolyte is added to the colloidal suspension, the colloidal particles attract the oppositely charged ions, and the difference in potential between the colloid particles and water decreases, increasing the surface tension. As a result, the colloid particles are drawn nearer together and are precipitated. Hence, the coagulation of organic matter, colloidal silica, and sulfur, can be effected by sea water, due to the presence of the needed electrolytes.

Experiments by prominent chemists have proved that the humus-acid groups, whose exact chemical composition is not well understood, can become colloids, and as colloids are easily precipitated by sodium chloride, calcium sulfate, and other salts. This fact probably explains the action of sea water in removing organic impurities from the river waters.

The gradual transformation of the organic hydrocarbons, precipitated by the electrolytes of the sea water, into the petroleum hydrocarbons could probably take place under several sets of conditions and would vary according to alkalinity, salts, and the presence of catalytic agents in associated formations, together with conditions of pressure and temperature. The evidence of action of sea water on waters of peat bogs seems to indicate that a slight amount of petroleum can be formed under proper conditions even where only normal conditions of pressure and temperature are present.

In the oil-shale beds of the west, intermediate organic compounds between the humus and paraffin hydrocarbons are apparently present, which require heat to change into petroleum. The character of the intermediate compound has been the subject of much discussion and comment, the prevailing idea being that the organic matter was chiefly carbonaceous and plant remains. However, microscopic studies of the shales have shown that while pieces of plants, pollen grains, seeds and spores are numerous in the shale with low oil content, the rich shales have virtually no plant or organic remains but apparently have some intermediate organic compound between the organic material and oil which may be changed to petroleum on application of heat and pressure.

---

## Production Problems in the Grass Creek Oil Field

By Edward L. Estabrook, Casper, Wyo.

THIS paper gives a brief account of the geologic and production problems encountered in the Grass Creek oil field, the methods used in their solution, and the beneficial results obtained from the work.

The Grass Creek oil field is in Hot Springs County, Wyo. The productive area includes about 2½ mi. on the apex of a great anticlinal fold occupying more than 150 sq. mi. Oil was discovered in the field in June, 1914; development proceeded rapidly and production rose to a maximum in 1918. The marketed production has been approximately as follows:

| | Barrels | | Barrels |
|---|---|---|---|
| 1915 | 94,073.5 | 1918 | 2,946,774.27 |
| 1916 | 1,404,183.97 | 1919 | 2,000,584.84 |
| 1917 | 2,780,697.51 | 1920 | 1,485,080.94 |

About 350 wells, 800 to 1500 ft. deep, have been drilled to reach the upper oil sands; two companies, the Ohio Oil Co, and the Midwest Refining Co., operate the entire field.

The principal producing sands in the field are members of the Frontier Formation, a series of sands and shales occurring in the upper portion of the Colorado Group of the Upper Cretaceous Series. These Frontier, or "Wall Creek" sands are also productive in the Salt Creek, Big Muddy, and Elk Basin fields and, therefore, are much the most important reservoirs of light oil in Wyoming. At Grass Creek, the sands in the Formation are more numerous than in the other fields and much less uniform in thickness and character. Usually, eight distinct beds are encountered and in some wells twelve sands have been reported.

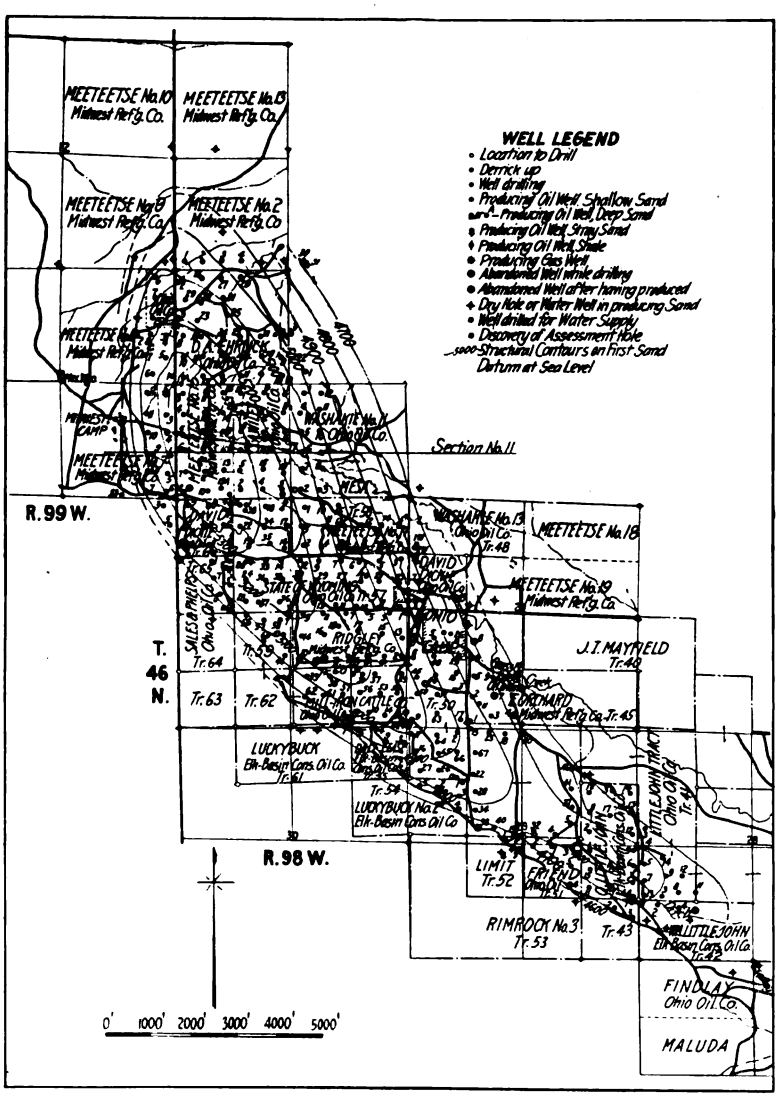
The upper, or First, sand in the Frontier Formation is reached at depths varying,from about 350 ft., in the center of the field, to 1000 ft. at the extreme edge. It ordinarily contains water in moderate amounts, but sometimes is so shaly and close-grained that very little water entered the well and it is reported in the logs as "dry." The Second, Third, Fourth, and Fifth sands produce gas in a small area at the apex of the dome and oil over the rest of the field. The Sixth, Seventh, and Eighth, sands are oil-bearing over the entire field. All of these sands contain water on the flanks of the anticline outside of the oil-producing area. The relative positions of the water lines (the oil-water contact) in the different sands have not been accurately determined, but the information available indicates no wide variation between them except in the Fifth sand.

Digitized by Google

At the north end of the field, water is found in that sand at least 200 ft. structurally above the water line in the other sands. Some of the first producing wells encountered three oil sands and then found water in the Fifth sand, so a rule was formulated that wells should be stopped after reaching the third oil sand.

The application of this "three sand" rule is responsible for the confusion in identifying the different sands, and for many of the water troubles in the field. The difficulty arose through the fact that a well drilled in an area around the apex of the anticline encountered several small gas sands, after passing through the water sand, and then found three good oil sands; while a well ½ mi. out would, at about the same depth, have encountered a water sand and then three good oil sands. Drillers accustomed to the gentle dips of the Mid-Continent fields quite naturally considered that the three producing sands in each well were identical and they were accordingly named the First, Second and Third sands. The water and gas sands were thought to be strays. Actually, the water sand encountered in both wells was the First sand of the Frontier Formation, the gas sands of the first well were the oil sands of the second, and the oil sands of the first were not reached by the second well. The well on the crest of the anticline had penetrated the entire series of Frontier Sands, while the well on the flanks was only half way through them. Intermediate wells encountered the first oil sands progressively higher in the Formation and were stopped after reaching the third oil sand.

The fact that many of the wells did not penetrate all of the oil sands in the Frontier Formation was noted in a report on the field by D. F. Hewett in 1917, but his findings did not receive the attention they deserved. In the course of some work on a revised structure-contour map of the field, during the winter of 1919, the writer arrived independently at the same conclusion. A comparison of graphic logs made it evident that a large percentage of the wells would tap additional productive sands if deepened from 10 to 150 ft. Where the lowest sand in the Frontier Formation had been reached in wells on the crest of the anticline, it had been found to be the most productive member in the group; yet over the greater part of the field it had not been touched. The fact that the production of the field had fallen off rapidly during 1919 gave added importance to the possibility of obtaining oil in the lower sands.



GRASS CREEK OIL FIELD.

The correctness of the conclusion that there were pay sands that had not been reached by many of the wells was tested by drilling well No. 18 on the Ridgley lease in the southern half of the southeast quarter of section 19. This well was put down through all the sands of the Frontier Formation and each one tested for its content of oil and water. The First sand was found to be water-bearing as usual; the Second, which had been an oil sand when the surrounding wells were first drilled, was partly filled with water; the Third and Fourth sands, which had been yielding oil in offset wells for several years, were still light producers; the four lower sands, which had not been reached in the vicinity, gave an initial production of 90 bbl. in 24 hr. when pumped on the beam. Seven months later, nine wells out of the eighteen on this lease had been deepened and the production had increased 250 per cent. Similar results are being obtained on other leases in the field.

The problem of stopping the circulation of water from the First sand downward, and later through unprotected sands, appeared to be one of great difficulty if undue expense was to be avoided.

# Personal Notes and Biographies

**W. L. Cumings** sailed for Chile on Jan. 7.

**Charles A. Dobbel** is assayer with the Patterson Mining Co., Tuttletown, Cal.

**G. E. Alderson** is metallurgist with the Duquesne Reduction Co., Pittsburgh, Pa.

**B. E. Moir** has been field engineer with the Atlantic Oil Producing Co. since last November.

**Alexander V. Dye** is American Trade Commissioner at the American Embassy, London, England.

**F. B. Forbes,** Lieutenant, 24th Infantry, has been moved from Manila, P. I., to Columbus, N. M.

**Harold A. Steven** is manager for the Henderson Farmers Lime, Ltd., at Beachville, Ont., Canada.

**O. F. Ernster** is with the Companhia de Petroleo de Angola, Loanda, Angola, Portuguese West Africa.

**R. A. Bull,** consulting engineer, has moved his office from Sewickley, Pa., to 639 Diversey Parkway, Chicago, Ill.

**Dwight L. Sawyer** has left Salt Lake City for Matahambre, Cuba, where he will be geologist for Minas de Matahambre, S. A.

**J. M. Longyear, Jr.,** has gone from Marquette, Mich., to Jimenez, Chih., Mexico, to be superintendent of the Julieta gold mine.

**Magnus Poulsen** was appointed some time ago to the position of Directeur Général de la Société Belge Industrielle et Minière du Katanga.

**John J. Moisan,** mill superintendent of the Benguet Consolidated Mining Co., Benguet, P. I., has been made assistant superintendent for that company.

**W. P. Gage,** recently with the Lone Star Gas Co. in Dallas, Tex., has moved to Houston, to enter the employ of the Humphreys Pure Oil Pipe Line Co.

**E. F. Davis,** recently with the Matador Petroleum Co., at Cheyenne, Wyoming, is in the geological department of the Shell Co. of California, San Francisco.

**Edgar Kraus** is geologist with the Atlantic Oil Producing Co., making his headquarters in Houston, Tex., and continuing his work in the Gulf Coast district.

**Gardiner M. Boyd** has left the Thetford mines of the Consolidated Asbestos, Ltd., and is with the United States Ferro-Alloys Corpn. at Black Lake, Que., Canada.

**R. M. Macaulay,** mining engineer for the Consolidated Mining & Smelting Co. of Canada, who has been investigating the phosphate industry in the western states, has returned from San Francisco to his home in Rossland, B. C.

**William W. Elmer** and **George C. Hogg** have an office in the United States National Bank Bldg., Portland, Ore., for consulting work in mining and civil engineering.

**Henry B. Smith** has left the New Britain Machine Co., New Britain, Conn., to work with G. J. Comstock in the laboratory of the International Silver Co., at Meriden, Conn.

**John K. Walsh,** recently returned from South America, has accepted the position of professor of mining engineering at the Oklahoma School of Mines, Wilburton, Okla.

**J. R. Thoenen** is general manager of the Spar Mountain Mining Co., at Cave in Rock, Ill. He is also consulting mining engineer for the Peerless White Lime Co. of St. Genevieve, Mo.

**Hugh M. Henton** has resigned from the faculty of the Case School of Applied Science and has opened an office for consulting work in metallurgy and mining, in the National City Bldg., Cleveland, O.

**John K. Knox** spent most of 1921 studying the petroleum resources of Baluchistan. He is now making an expedition for the Whitehall Petroleum Corpn., into some of the less explored parts of Burma.

**J. B. McGraw** recently severed his connection with the General Briquetting Co. of New York, after five years service as fuel briquetting engineer, to become manager of the Anthracite Briquette Co. of Canada, Ltd., at Toronto, Ont.

**H. C. George,** with the Petroleum Division of the U. S. Bureau of Mines, recently completed a five-months trip through the California, Wyoming, Mid-Continental and eastern oil fields. Mr. George is making a study of surface equipment of pumping oil well properties.

**W. R. Ingalls** has written a treatise on the "Wealth and Income of the American People," which will be published by the G. H. Merlin Co. (York, Pa.) early in February. It is an economic survey of the consequences of the war and carries forward much of the thought that Mr. Ingalls has expressed in contributions to MINING AND METALLURGY and other periodicals. It is an elaborate essay into the field of quantitative economics. It inventories in great detail the wealth of the country in 1916 and in 1920, gives the national income over a series of years, computes the national living expenses and gives a balance sheet showing how we stand. It is, in short, a comprehensive analysis of our national finance and industrial affairs.

## Edward Crawford Arnold

EDWARD CRAWFORD ARNOLD, general mine foreman for the Federal Lead Co., Flat River, Mo., died at his home in Farmington, Mo., on Dec. 7, 1921, after a brief illness. Mr. Arnold was born in Graham, Tex., Nov. 22, 1885, the son of Judge Robert F. and Catherine Arnold.

After completing the course at the Graham High School, he attended the A. and M. College of Texas from which he graduated in 1906 with the M. E. degree. He was instructor in the Manual Training High School, Marlin, Tex., for a year and engineer for the Wichita Falls and Southern Railway another year and then went to Inde, Dgo., Mexico, as shift boss at the cyanide plant of the Inde Gold Mining Co. In 1909 and 1910, he attended the University of Texas, at Austin, and specialized in mining; then returned to the Inde Gold Mining Co., holding the positions of mill shift boss and assayer until the fall of 1913, at which time he returned to the United States on account of troubled conditions in Mexico. He then accepted a position with the Federal Lead Co., at Flat River, Mo., where he held the positions of assistant engineer, assistant in experimental plant, chief engineer and general mine foreman.

Mr. Arnold had a remarkably even temper and a sunny disposition and was universally esteemed and admired by both his business and social associates.

He was married in 1915 to Miss Ethel Morris of Farmington, Mo., who survives him.

---

## James Duane Ireland

JAMES DUANE IRELAND died on Dec. 6, 1921, at Cleveland, Ohio, after an illness of several months. He was 43 years old.

Mr. Ireland was graduated from Yale in 1900, and received degrees in Mining and Mechanical Engineering in 1902 and 1903 at the Massachusetts Institute of Technology. His activities in the mining field commenced immediately after this. He was employed at the Camp Bird mine in Colorado, then spent a few years prospecting in Arizona, Southern California and northern Mexico. In 1907 he became mining engineer for M. A. Hanna & Co. of Cleveland, Ohio, and took up his duties on the Mesaba and Michigan Ranges.

In 1908, Mr. Ireland was appointed general manager of the iron-ore properties of this company, and opened offices in the Sellwood Building, Duluth, Minn. He continued in this capacity until 1917, when he was made a member of the firm and left for Cleveland.

Under Mr. Ireland's managership, a number of original ideas were successfully developed, among which can be classed: (1) Drying iron ores before shipment from the mines, as a means of rendering commercial a number of ores, which on account of excessive moisture are not merchantable. The first plant for this purpose, an experimental one, was built in 1909 at the old Hollister mine near Crystal Falls, Mich., and was followed by large plants built at the Brunt mine near Mountain Iron, Minn., and at the Wakefield mine, Wakefield, Mich. (2) The first mill in the Lake Superior region using jigs for the concentration of banded ores. This mill was built in 1911 at the American mine, near Ishpeming, Mich. (3) The method of stripping on the Mesaba Range by means of a large revolving dragline machine, in such a way as to overcast the spoil from the first cut and then recast this material to make room for depositing the spoil from a second cut, all this being accomplished without the use of locomotives and dump cars. (4) The use of the first all electric shovel on the Mesaba Range. Mr. Ireland was among the first to recognize the advantages of using electrical apparatus at the iron-ore mines in the Lake Superior region, and to adopt a policy of complete electrification.

After Mr. Ireland moved to Cleveland, he was elected vice-president in charge of the operation of the Susquehanna Collieries Co., which constituted the company's holdings in the anthracite region. Under his direction a complete rehabilitation was undertaken, which involved electrification of 14 collieries, with the construction of three central-power stations, each having a capacity of 15,000 kw. and one of 2000 kw.; the sinking of new shafts, and building new breakers as a means of eliminating old and inefficient ones, and in some cases concentrating a number of collieries into one breaker with the same object in view. This work was started in 1918 and a large part had been completed at the time of his death.

He leaves a widow, Elizabeth Clark Ring Ireland, and one son, James Duane Ireland, Jr., eight years of age.

R. S. WALKER.

---

## De Bernier Whitaker

DE BERNIER WHITAKER, vice-president and general manager of the Bethlehem-Cuba Iron Mines Co., died at Santiago de Cuba, Cuba, Dec. 25, 1921, at the age of 52.

Mr. Whitaker was educated at the University of North Carolina. He became connected with the Maryland Steel Co. of Baltimore and then went in 1898 to Santiago de Cuba as chemist for the Spanish-American Iron Co. Later he became general superintendent of the Juragua Iron Co., a subsidiary of Bethlehem Steel Co., and upon the purchase by Bethlehem of the properties of the Spanish-American Iron Co. he became vice-president and general manager of all their iron mines in Cuba.

Mr. Whitaker became a member of the A. I. M. E. in 1899. He was also a member of the Engineers Club, New York.

## Strangman Hancock

STRANGMAN HANCOCK, who died on Oct. 29, 1921, at the age of 56 years, was the younger son of the late Thomas Strangman Hancock of Lisburn, Ireland. He followed the profession of mining engineering, first in North Carolina and later in South Africa, for 25 years.

He served in the South African war, first as captain in the Railway Pioneer Regiment, later in the Rand Rifles, and held the appointment of J. P. while in that country. He went to reside at Kennel Holt, Cranbrook, Kent, in 1909 and was appointed J. P. for the county in 1912. He was also a Commissioner of Taxes and a Lunacy Commissioner. He sat on the Cranbrook Rural District Council for several years and was a director of the Cranbrook Water Works until the time of his death. During the past year he held the appointment of supervisor of the special constabulary of this district.

He served as captain on the General Reserve from 1914 to 1916 and at one time was commandant of three ships of prisoners of war.

Mr. Hancock joined the A. I. M. E. in 1889.

## Samuel M. Keiper

SAMUEL M. KEIPER, a retired mining engineer, formerly president of the Red Star Powder Co., died suddenly at his home in New York, on Jan. 8, 1921. He was born at Middletown, Pa., 77 years ago.

Mr. Keiper entered the mining field early in life, and followed this work by the manufacture of explosives. He retired from active business about ten years ago.

He became a member of the Institute in 1916, and was a charter member of the Pennsylvania Society.

## Necrology

THE deaths of the following members were reported to the Secretary's office during the month Dec. 17, 1921 to Jan. 14, 1922.

| Date of Election | Name | Date of Death |
|---|---|---|
| 1917 | Arnold, E. C. | Dec. 7, 1921 |
| 1911 | Chase, Fred M. | April 8, 1921 |
| 1881 | Colvin, Verplanck | May 28, 1920 |
| 1905 | Ireland, James D. | Dec. 6, 1921 |
| 1921 | Jennings, C. F. | 1921 |
| 1916 | Keiper, Samuel M. | Jan. 8, 1922 |
| 1913 | Murphy, James K. | 1921 |
| 1921 | Showalter, James Robinson | |
| 1899 | Whitaker, De Bernier | Dec. 25, 1921 |

**Neither Engineers** nor scientific men have any right to prefer their own personal peace to the happiness of mankind; their place and their duty are in the front line of struggling humanity, not in the unperturbed ranks of those who keep themselves aloof from life.—Korzybski.

## Masks Insufficient Protection in Fire-fighting

GASES and vapors may cause three atmospheric conditions dangerous to life. Dr. H. Foster Bain, director of the United States Bureau of Mines, has issued a statement regarding these conditions, in which he gives the following information and advice.

First, in warfare, there are poisonous gases from shells or bombs which, as they are discharged usually in the open air, occur in low concentrations; that is, the actual percentage is small and there is no material depletion of oxygen. This condition was met efficiently by the army gas masks.

Second, in industries, high concentrations of such gases as ammonia, sulfur fumes and carbon monoxide may be encountered through accidents or repair work, though usually there is plenty of oxygen in the air for breathing. This condition may be met by the use of masks with special absorbents. Army masks are valueless for carbon monoxide and high concentrations of ammonia and many other gases.

Third, in confined spaces, such as in tanks, basements and in mines, following explosions or fires, there may be poisonous gases, fumes or inert gases in such quantity that the oxygen content may be so reduced that the atmosphere will not sustain life, independent of the toxic effect of the gases. In this condition, no mask is of any value.

Use of army masks and other masks has led to a number of deaths in fire fighting, in cleaning gasoline tanks, and in entering mines in which there have been fires. Only self-contained breathing apparatus that supplies abundant oxygen is of avail in these places.

A mask has been developed by the Bureau which will allow the wearer to enter smoke and fumes given off in the open air or in large open buildings, but it must be borne in mind that when there is deficiency of oxygen, as in mines after explosions or fires, in confined spaces, in surface fires, in basements or closed rooms or where illuminating gas or gasoline vapor may be present in high concentration, only self-contained breathing apparatus, otherwise termed oxygen breathing apparatus, can be safely used.

Insufficiency of oxygen gives no warning. Rapid changes may occur in the air of a mine after an explosion or during a fire, and a man wearing a gas mask may drop without warning when he encounters an atmosphere deficient in oxygen. The Bureau therefore recommends, on the basis of present evidence, that only self-contained oxygen breathing apparatus should be used in mines following explosions or fires.

There are always men willing to risk their lives to save others who would be tempted to use masks if they were on hand, and the risk is larger than should be taken.

## A. S. M. E. Annual Meeting

MORE than one hundred professional events, together with numerous social meetings, contributed to the success of the five-day meeting of the American Society of Mechanical Engineers in December.

Elimination of waste in industry, education and training in the industries, engineering education, and topics of special interest to mechanical engineers were discussed at the 19 technical sessions.

The first award of the A. S. M. E. Medal was made to Hjalmar G. Carlson for his invention and part in the production of 20,000,000 Mark III drawn steel booster casings used principally as a component of 75-mm. high-explosive shells, and also extensively in gas shells and bombs.

Honorary membership in the Society was conferred on Henry R. Towne, of the Yale & Towne Mfg. Co.

Dexter S. Kimball, dean of the College of Engineering at Cornell University, was elected president of the A. S. M. E. for the year 1922.

---

## Association of Technical Societies founded in Detroit

AFTER several years of thought and discussion, the movement for the affiliation of the architectural, engineering and other technical societies of Detroit was taken up seriously in June, 1921, by the organization of a temporary council composed of two delegates from each of the several societies interested. The affiliation has become an accomplished fact, taking effect Jan. 1, 1922, by the ratification of the proposed Constitution and By-Laws, acceptance of membership and election of Councillors by the following twelve societies: Detroit Section, American Society of Civil Engineers; Detroit Chapter, American Association of Engineers; Michigan Chapter, American Society of Heating and Ventilating Engineers; Detroit Post, Society of American Military Engineers; Detroit Section, American Society of Mechanical Engineers; Detroit-Ann Arbor Section, American Institute of Electrical Engineers; American Institute of Chemical Engineers; Detroit Engineering Society; American Chemical Society and Detroit Chemists; Michigan Chapter, American Institute of Architects; Detroit Section, Michigan Society of Architects; Detroit Chapter, American Society for Steel Treating.

The permanent council met and organized Dec. 13, 1921 and elected officers for 1922 as follows: chairman, P. W. Keating; vice-chairman, A. A. Meyer; secretary-treasurer, Walter R. Meier.

A central office will be established for conducting the business of the several societies. In the past, the meetings of the various societies have often occurred on the same date. This conflict of dates will hereafter be avoided, as the office of the new association will schedule the dates of meetings of all the technical societies. The Associated Technical Societies of Detroit will provide one meeting each month, which will be under the management of one of the member societies.

The paramount use of the new association to its members and to the public is its opportunity for public service both for the city of Detroit and for the state of Michigan. The association will take an active interest in all matters wherein engineering, architectural and technical subjects are an important factor, and will give assistance to city and state officials whenever required.

---

## Engineering Section of A. A. A. S. Toronto Meeting

THE meeting in Toronto, Dec. 27–30, of the Engineering Section of the American Association for the Advancement of Science was full of interest and was attended by many representative men of the engineering, geological and university life of the United States and Canada. The chairman of the section is J. B. Tyrrell, member of the A. I. M. E.

At the techincal sessions of the first three days, various engineering subjects were discussed, in papers on natural resources, transportation, power, and mining of coal, metals and oil. The last day's sessions were under the auspices of the Society for Promotion of Engineering Education.

At the dinner on Thursday evening, Mr. Tyrrell was toast master, and the speakers included Dr. F. G. Cottrell, chairman of National Research Council, Washington, D. C.; Sir Robert Falconer, president of the University of Toronto; Prof. E. H. Moore, ex-president of the American Association for the Advancement of Science; Prof. B. E. Livingston, permanent secretary of the American association; Prof. D. T. MacDougal, general secretary of the American association; Hon. H. Mills, Ontario Minister of Mines; Principal M. Hutton, of University College; Prof. C. R. Young and Brig.-Gen. C. H. Mitchell, dean of the Faculty of Practical Science.

---

## Free Information

THE Research Information Service of the National Research Council is prepared to supply information about scientific instruments, apparatus and supplies, laboratory construction and equipment.

The following are samples of requests answered recently: "Where may we purchase inexpensive photomicrographic apparatus?" "Where may a human skull be purchased?" "Who manufactures a good grade of selenium cells?"

Address your requests: National Research Council, Information Service, Washington, D. C.

# Institute Affairs

## The Home of the Institute

ONE DAY early in December, a member of five years standing called at the office of the Institute for the first time since joining. He was shown over the offices, the library, the meeting rooms and auditorium. As he was preparing to leave he remarked, "Mr. Secretary, our excursion through the splendid quarters of the Institute produces two conflicting sensations; the one is that the building graces with becoming dignity an organization to which I have felt it an honor to belong, it is emblematic of my ideal of the Institute; the other is that it looks as though the resources of the Institute, its members' dues, were being used for the purpose of making a show rather than for the objects mentioned in its Constitution."

This observation caused the Secretary to recite a bit of history which it may be wise to repeat for the benefit of other members who have joined the Institute within recent years.

It is now nearly twenty years since Andrew Carnegie became interested in the affairs of the four Founder Societies, the Civil, Mining, Mechanical and Electrical Engineers. He saw them struggling along in cramped quarters, spending much of their income for inadequate office accommodations and, as a result of his observations and the representations made to him, he sent in March, 1904, a letter to the Mining, Mechanical and Electrical Engineers from which the following is quoted.

"It will give me great pleasure to devote, say, one and a half million dollars for the erection of a suitable union home for you all in New York City."

The Civil Engineers did not deem it wise to participate at that time, but the other three national engineering societies proceeded to raise more than half a million dollars with which to purchase the land on which the building was later erected.

Of the equity owned by the Mining Engineers, about 80 per cent. or $400,000, was raised by voluntary contribution, while only about $86,000 has been paid out of dues.

Today the members of the Institute hold a quarter share in a building that could not be duplicated for $3,000,000, and in a library and securities valued at another $1,000,000. The building is used now not only by the four national engineering societies, but by eighteen other engineering societies whose rents largely pay the operating expenses of the building.

In addition to office accommodations, the Institute has available for its meetings an auditorium and a number of smaller rooms suitable for section gatherings and, above all, it has at hand a splendid library of technical literature, so managed that its service is available to every member in every land.

Thus we see that the second thought of our visitor was based on a misconception. It was the generosity

ENGINEERING SOCIETIES BUILDING, NEW YORK CITY.

of Andrew Carnegie and that of a number of our members that gave us an asset which could never have been acquired through the payment of dues, an asset which is in keeping with the character of the organization.

The stars and stripes are emblematic to each citizen of that which he feels the flag should stand for. So with our monumental home; it is merely a show place, or it is a fitting habitation for a dignified and influential organization such as each member strives to maintain.

F. F. SHARPLESS.

## Related Activities

TO MEMBERS not closely in touch with the work of the Institute, to those who note the long list of boards or committees upon which the Institute is represented, the thought has come sometimes that the Institute may be expending its efforts and resources in directions not contemplated in its Constitution. That this thought should come is not strange, but it would rapidly be dispelled if the questioner had an opportunity to read the Constitution and By-laws of one after another of these organizations and thus learn what each is doing and how its work is being done. He would first learn that he is contributing little or nothing in a financial way to these societies and committees and then he would learn that time, thought, effort, and in some cases financial help are being given liberally and unselfishly by many of his fellow members toward a work that at least they think is well worth the doing.

Of most immediate interest to the Institute, perhaps, is the United Engineering Society, composed of three trustees from each of the four Founder Societies. This Society holds the title to nearly $3,000,000 worth of property belonging to its constituent members and administers trust funds amounting to over $700,000.

The libraries of the four societies were combined and are now cared for by United Engineering Society and a committee of members functioning under its supervision.

In 1914, Mr. Ambrose Swasey of Cleveland offered to the four national engineering societies the sum of $200,000, the income of which should be devoted to research in science and engineering. Another group of men was called upon for service and Engineering Foundation was formed as a part of United Engineering Society to use these funds as seemed wise. The writer had the good fortune to attend a recent meeting of the Foundation and to listen to the discussion of progress which has been made in various lines. Mr. Swasey was present and when asked to speak remarked, "Yes, I have one thing to say. It is most gratifying to me to be here and to realize that such a large number of very busy men are always ready to give so much of their time to a purely altruistic enterprise, without thought of or possibility of reward." Through Mr. Swasey's further gifts, the funds in the hands of the Foundation have grown to $500,000.

National Research Council, created in 1916 as a department of the National Academy of Science, is another of the voluntary organizations in which Institute members take active part. This organization, with the financial assistance of Engineering Foundation and the coöperation of the University of Illinois, as a third party, has recently completed an interesting series of experiments on a limited group of steels. In 1920, the General Electric Co., recognizing the splendid work that was being done, added $30,000 to the funds available and the work has been continued to a broader series of metals. A progress report has been issued by the University of Illinois, as Bulletin 124.

Engineering Council, starting as a joint Conference Committee of the four Founder Societies, was created in 1917 to deal chiefly with non-technical matters. During the war it aided the army and navy and the departments of the Government in selecting techincal men for special service. It assisted the Naval Consulting Board and General Staff in examining 135,000 suggestions and inventions for war service. Since the war it has coöperated with our Employment Bureau and has been active in Washington assisting in the reorganization of departments with the object of economy and simplication. Later, it assisted in the formation of its successor, American Engineering Council, of the Federated American Engineering Societies, whose achievements during the first year of its existence were noted in the December issue of MINING AND METALLURGY.

The federation is an organization to which all members contribute, but their contributions are insignificant compared to the work of individual members who are striving to make it the national mouthpiece of the engineering fraternity.

Members contribute a trifle also to American Engineering Standards Committee, but here again the real support of this organization is the devoted work of the men who are contributing generously of their time and thought to the development of national standards for the benefit of all engineering industries.

And so it goes through all the long list of committees and organizations listed in our Year Book. Most of the names appearing under them are workers and are glad of an opportunity for work on a line of enigneering industry in which they are interested. The lists would be even longer except for the fact that many members have not signified their desire to work on such committees or their ability to do so has not been made known to the officers of the Institute.

Through a questionnaire that was sent out on Dec. 10, it is hoped to learn of the special interest of each member. If the response to this is as full and generous as is hoped for, the information will be most valuable to the officers of the Institute in giving to members that which will be most useful to them and in securing from members that service and knowledge which it is believed that all are ready to give when called upon.

F. F. SHARPLESS.

## Molding Sand Research

HUNDREDS of thousands of tons of molding and core sands are used annually in the iron, steel and non-ferrous foundries of America. A little of it is re-used; much more might be. Sands are not always correctly selected for specific purposes. Mixing and other treatment can secure improvement. In what

Digitized by Google

ways can foundry practice as to sands be bettered? What economies can be realized, not only in reduced expenditure for sand, but also in less number of lost castings and higher quality of accepted product?

Last spring, the American Foundrymen's Association decided that thorough study of this subject would be profitable and asked the coöperation of the American Institute of Mining and Metallurgical Engineers. The Institute referred this request to the Division of Engineering of National Research Council, of which it is a member. Through joint action with the Division, a valuable digest of the literature has been made by Professor Robert E. Kennedy, of the University of Illinois, and a large committee of foundrymen, engineers and scientists has been selected, under the general direction of President W. R. Bean, of the Foundrymen's Association, and the chairman of the Division.

This committee on Molding Sand Research was organized in November, with officers and executive committee as follows:

Chairman, R. A. Bull, Consulting Engineer, Sewickley, Pa.

Secretary, Robert E. Kennedy, Urbana, Illinois, Assistant Secretary, American Foundrymen's Association.

W. R. Dean, Naugatuck, Conn., President, American Foundrymen's Association

Henry B. Hanley, Metallurgist and Chemist, New London, Conn.

Jesse L. Jones, Metallurgist, Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.

Henry Ries, Professor in Department of Geology, Cornell University, Ithaca, New York.

Bradley Stoughton, Consulting Engineer, New York City.

George K. Burgess, Chief, Division of Metallurgy, Bureau of Standards, Washington, D. C.

The committee has 35 members, representing the many interests in the use of molding sand. The coöperation of men having like interests in Canada and England is assured and invitations have been extended to France and Belgium.

ALFRED D. FLINN.
*Chairman, Division of Engineering, National Research Council.*

---

## American Engineering Standards Committee

UNTIL about a year ago the work of the American Engineering Standards Committee was mainly in developing an organization and determining methods by which its work could be made effective. As the whole idea of such a committee was entirely new, much time was required to arrange a procedure that would insure coöperation of the different interests with a minimum of friction. We believe that the progress made in the past year shows that the methods adopted are working well. In several cases in which different bodies had started standardization work on closely related subjects we have been able to get them to work together harmoniously and effectively.

During the year we have established much closer and more satisfactory relations with similar bodies in other countries, and in at least one case a project of international standardization is now under way, with a sectional committee of the A. E. S. C. acting for this country.

Last April, Doctor Agnew, secretary of the committee, attended a conference of the secretaries of the different national standardization bodies, in London. The result of the conference was most satisfactory, arrangements having been made for the prompt interchange of information and for coöperative work in many directions. Following the meeting in London, Doctor Agnew visited the Continent and obtained much interesting and valuable information, particularly in Germany, where standardization is very active. His report on standardization in Germany is now available.

During the year several additional organizations have become members of the committee; others have applied for membership, but their applications have not yet been passed upon by the present member bodies. The committee now consists of 49 members, representing most of the technical and commercial bodies that are actively interested in engineering standardization.

The question of finances is, as with all similar bodies, a difficult one. The expenses of the Committee are not large, the only paid officer being the secretary, who has a small office in the Engineering Societies Building, with a very small force of stenographers. The only other expenses are printing, postage, and traveling expenses of the secretary. The present income is entirely inadequate for the work that should be done, and the finance committee of the A. E. S. C. is actively at work on plans to secure additional income. The Committee fully realizes that many of the member bodies are not in a position to increase their contributions, and that the expenses should be mainly borne by those who benefit most directly by standardization.

Briefly, during the past year:

The Committee has become broadly representative of standardization interests by the inclusion of additional member bodies. It has improved and made more effective its relation with other national standardization bodies. It has materially assisted in securing the coöperation of different bodies interested in the formulation of similar standards. It has lived within its income and is making plans to secure sufficient money to enable it to do the things it was organized to do.

Several correlating committees have been formed that are defining the work of the sectional committees and advising the A. E. S. C. and sponsor bodies regarding it. In all, 37 sponsors have been appointed and and the sectional committees, including representatives of 180 organizations, appointed by them are actively engaged in formulating standards.

GEORGE C. STONE.

## Neglect of Reduced-fare Privilege Cost Members of the A. S. M. E. $1750

THE following sentences are copied from the news bulletin of the American Society of Mechanical Engineers:

"Out of a registration exceeding 1800 members and guests, less than 350 members who attended the Annual Meeting filed railroad certificates. Thus the fare and a half privilege was not obtained for the 260 who were thoughtful enough to secure and hand in reduced-rate certificates, and who sustained a loss of $1750. It is estimated that $4000 might have been saved by members of the Society if all who were eligible to receive reduced-fare certificates at the time of purchasing transportation to New York had exercised the right.

"The Society itself also might have saved over $1000 in mileage of its members of Council and Sections' delegates, if the fare and a half privilege had been secured."

Unless members of the American Institute of Mining and Metallurgical Engineers are more active in this direction, there will be a similar report after our annual meeting. If you will read the directions either in the January MINING AND METALLURGY or in the announcement sent out on Jan. 20, and will keep in mind the welfare of your fellow members and of the Institute, you will ask for a *certificate* when you buy your ticket to New York.

## Library Book Loans

THE Library Board has adopted rules authorizing the Director of the Library to lend any duplicate books in the Library to members of Founder Societies or of any other societies that contribute to maintain the Library, subject to the following rules:

Books will be lent for 28 days, including time in transit.

Five cents a day will be charged for each book kept longer than 28 days.

Borrowers shall be responsible for books borrowed, and shall pay shipping and insurance charges from and to the Library.

The Library has several thousand volumes that can be lent under this authorization. These include a considerable number of textbooks, reports, etc. of various dates. Periodicals are not included, as the cost of storing duplicate sets seems prohibitive and individual articles can be photoprinted at little expense. The collection is being increased regularly by the addition of suitable duplicates received by the Library. Members are invited to present books of permanent value for this purpose, which they can spare from their libraries. It is hoped that the collection may in time become adequate to meet the usual needs of members by providing standard books for a short time.

No catalog of these books has been published, although it is hoped that one may be printed when the collection becomes extensive enough to warrant it. Until that time, the Director will be glad to receive requests and report as to whether or not the books are available.

HARRISON W. CRAVER,
*Director of Library.*

## Institute Transactions

VOLUME LXIV, containing papers on Non-ferrous Metallurgy and Metallography, has been sent to all members who have asked for it. If there are any members who desire this volume and who have not yet received it, will they please communicate with the Secretary.

Volume LXV, containing papers on Petroleum and Gas, is now in the hands of the binder and will be issued in February.

Volume LXVI, consisting of papers on Mining, Milling, Geology and Coal, is now in the hands of the printer and will be issued early in the year.

Volume LXVII will be printed later in the year.

## Coming Meetings of Societies

| Organization | Place | Date |
|---|---|---|
| **Amer. Inst. Min. & Met. Engrs.** | **New York, N. Y.** | **Feb. 20–23** |
| Amer. Ceramic Soc. | St. Louis, Mo. | Feb. 28–Mch. 3 |
| Canadian Inst. of M. & M. | Ottawa, Ont | Mch. 1–3 |
| Amer. Chem. Soc. | Birmingham, Ala. | April |
| Amer. Welding Soc. | New York, N. Y. | April 27 |
| Iron & Steel Inst. | London, England | May 4–5 |
| Amer. Zinc Inst. | St. Louis, Mo. | May 8–9 |
| Amer. Soc. Mech. Engrs. | Atlanta, Ga. | May 8–11 |
| Foreign Trade Convention | Philadelphia, Pa. | May 10–12 |
| Amer. Foundrymen's Assn. | Rochester, N. Y. | June 5–10 |
| Amer. Soc. for Test. Mats. | Atlantic City, N. J. | June 26–July 1 |

**In the United States,** the coal-mining industry employed 4000 more men in 1920 than in the preceding year. The copper-mining industry suffered a loss of 4000 men; the iron-mining industry, a loss of 1700; and the gold and silver mines, a loss of 2200 men. A loss of 1300 employees occurred in the lead, zinc and fluorspar mines in the Mississippi Valley states. The quarries of the country gained 11,000 employees. There was a loss of 4200 employees at metallurgical plants and 600 at coke ovens. In 1920, all employees averaged a larger number of working days than in 1919. The gain among workers in metal mines averaged 15 days per man. Quarrymen gained 14 days each. Workers at beehive coke ovens gained 32 days per man while those at byproduct ovens gained 18 days each. Coal-mine employees gained an average of 32 days for each of the 780,000 men employed last year.

# Activities of Local Sections and Affiliations

## Sulfur Discussed for Ohio Section

THE regular meeting of the Ohio Section for the month of December was held on the 19th, in the rooms of the Cleveland Engineering Society. Fourteen members attended the dinner that preceded the meeting, and 40 members and guests were present during the evening.

During the dinner, L. C. Drefahl talked very entertainingly on the subject of sulfur, and gave many interesting facts about the sulfuric-acid industry. In the evening, after various business details had been discussed by the section, the moving picture, "The Story of Sulfur," was shown.

## Story of Tungsten Told for Chicago Section

THE Chicago Section of the A. I. M. E., on Jan. 5, 1922, held a joint meeting with the Western Society of Engineers and the Chicago Section of the American Institute of Electrical Engineers, preceded by an informal dinner at the Engineers Club.

Dr. W. C. Blake, chief metallurgist for the Fansteel Products Co., manufacturers of metallic tungsten and molybdenum, addressed the gathering on "The Story of Tungsten." He gave a brief history of the progress that has been made in the metallurgy and uses of this metal, taking up its physical and chemical characteristics and modern commercial applications. He touched on the occurrence of tungsten ores in the United States and outlined the treatment of these to produce concentrates which his company and other manufacturers of tungsten purchase in the open market. These concentrates must be very carefully refined to produce an almost chemically pure tungsten oxide. Doctor Blake explained in detail the interesting process of the reduction of this oxide to the metallic element in an electric furnace, the consolidation of the amorphous powder thus obtained into a billet which is then treated by passage of an electric current to produce cohesion and promote grain growth, and the treatment of the ingot thus obtained, which is swaged to cylindrical form and reduced in diameter by further swaging and drawing through diamond dies.

The talk was illustrated by lantern slides showing the processes in the metallurgy and production of pure tungsten and by some very illuminating photomicrographs showing the grain structure, and grain growth through the application of heat, with later elongation and deformation of the grains through mechanical working. Through the courtesy of the General Electric Co., a film illustrating the manufacture of tungsten lamps was shown.

This was one of the most interesting and successful meetings that the Chicago Section has enjoyed. The total attendance was about one hundred and fifty.

## Copper and Asbestos Interest San Francisco Section

AT THE meeting of the San Francisco Section on Dec. 27, attended by 30 members and guests, the speaker of the evening was Dr. H. W. Morse. His address, on the Present Status of the Treatment of Mixed Copper Ores, was comprehensive and brought out interested general discussion.

On Jan. 10, the section elected its officers for the year. Albert Burch was made chairman; T. J. Hoover, vice-chairman; C. H. Fry, secretary-treasurer; Jules Labarthe and Walter S. Weeks, members of the executive committee.

W. J. Woolsey spoke on Asbestos in California and its Relation to the Quebec Industry, which proved so interesting to his hearers that general discussion was maintained until an unusually late hour for a section meeting. Mr. Woolsey told of the methods of mining and milling asbestos in Quebec, and of the similarity between the Quebec deposits and those of California.

It was decided that the subject for discussion at the next meeting of the section should be Revision of the Mining Law.

## New York Section Votes to Fight Licensing

THE regular monthly meeting of the New York Section was held on Jan. 11, 1922. In the absence of the chairman, in Burma, the vice chairman, William Young Westervelt, presided. There were 65 members and guests present for the dinner and about 90 for the program.

The subject for the evening was "Compulsory Licensing of Mining Engineers—Are You in Favor of Personally Paying $1200 to Secure Licenses to Practice in 48 States?" The speakers were Percy E. Barbour, John M. Goodell, B. Britton Gottsberger, Frederick

Digitized by Google

Tabor Rubidge, A. S. Dwight. Others joined in the discussion.

It was moved, seconded and unanimously carried, except one vote to the contrary, that a resolution be addressed to the Board of Directors, and spread on the minutes, as follows:

WHEREAS the Legislature of this State has passed a law requiring that engineers be licensed for the practice of their profession, and

WHEREAS it is our belief that this law or any other law for the licensing of engineers does nothing to improve the status of the engineer and is not required for the protection of the public, and

WHEREAS this law imposes an unjust and burdensome restriction on engineers in the practice of their profession, be it

RESOLVED that the members of the New York Section of the American Institute of Mining and Metallurgical Engineers present in meeting assembled pledge themselves jointly and severally to work for the repeal of this law and to oppose any similar legislation.

RESOLVED that a copy of these resolutions be transmitted to the Board of Directors of the A. I. M. E., with the request that the appointment of a committee of five by the chairman of the section be approved, said committee to plan and carry out measures for the repeal of the New York licensing law, and to this end authorized to receive and disburse funds and to coöperate with other engineering organizations.

## Boston Section Holds Interesting Meetings

THE 70th meeting of the Boston Section was held on Nov. 7. Chairman W. Spencer Hutchinson presided, and 58 members and guests were present.

Professor Hayward gave a brief description of the Chicago meeting of the American Mining Congress and Exposition of Mining Equipment, which he attended.

Prof. Waldemar Lindgren, just returned from South America, gave a talk on the Geology and Mines of Bolivia, and an interesting description of the people of that country, and showed some excellent lantern slides.

At the 71st meeting, on Dec. 5, 40 members and guests were present. The secretary read the report of a plan for consolidating the administrative work and headquarters of the engineering and technical societies of Boston. This plan, prepared by a joint committee of representatives from the various societies, provides for:

1. A consolidation of the administrative work of the societies in the hands of a council consisting of two councillors from each society.
2. The employment of a paid secretary and office force.
3. The use of the present quarters of the Boston Society of Civil Engineers in Tremont Temple building.
4. That the name of the organization be The Associated Technical Societies of Boston.

The advantages and disadvantages of such an arrangement and the obstacles in the way of its accomplishment were discussed, the general sentiment being that such a consolidation is desirable. Considerable doubt was expressed, however, regarding the possibility of making financial arrangements that would not be a serious burden to the Boston Section. A committee was appointed to consider this matter, and to report to the section.

The speaker of the evening, F. W. Denton, vice-president of the Copper Range Co., talked on Mining Methods at the Copper Range Mines, and showed lantern slides illustrating these methods. Many of the photographs for these slides were taken underground. Mr. Denton also showed some interesting pictures of old-time mining devices and equipment, such as the "man-engine" used in the copper country in the early 90's.

## Columbia Section Annual Meeting

AT NOON on Dec. 28, the Columbia Section had charge of the meeting of the Associated Engineers, in Spokane, Wash., at which 85 members and guests were present. D. F. Henderson, president of the Associated Engineers, was in the chair, and Senator Miles Poindexter was the guest of honor.

Rush J. White, Francis A. Thomson, Sidney Norman, and others spoke on Revision of the Mining Law. None favored the proposed revision as a whole, but admitted that some changes in the present law are desirable. Senator Poindexter said that he was glad to have the opinions of local engineers and mining men. He urged that in this period of reconstruction every citizen should aid by constructive suggestion and work, and that each should exercise unusual patience with his neighbor, with Congress and with the Administration.

In the evening, the eleventh annual meeting of the Columbia Section was held at the Davenport Hotel, Spokane, beginning with a dinner at which about twenty ladies were present as guests of the members. At the business session following the dinner, chairman Ivan de Lashmutt presided. Officers for the next year were elected as follows: Rush J. White, chairman; Frank M. Smith, vice-chairman; L. K. Armstrong, secretary-treasurer.

The subject for the evening was "The Geology of the Northwest, with Special Reference to the Economic Possibilities." The principal address was made by Prof. O. P. Jenkins, associate professor of economic geology at the State College of Washington. Professor Jenkins said, in part:

It is a mistake to consider geology as a subject limited only to the study of the occurrence of mineral deposits. To be sure, that phase of the work is vital, but we should not limit our viewpoint in that manner. The Spokane Falls are a geological feature, and they were, I understand, instrumental in the location of this city. The Palouse country, with its great wheatfields, exists because of the occurrence there of one of the greatest basalt flows of the world, and because fertile soil is formed from the weathering of basalt under favorable conditions. Puget

Digitized by Google

Sound, with its bordering cities, fairly boiling over with industry, exists because of a subsidence of the land and an encroachment of the ocean water into old stream channels. Hardly a single industry may be established that is not directly or indirectly affected by geological conditions.

I find that the greatest handicap we engineers and geologists have to contend with is that we do not know the detail of industry. I mean that if we knew just what industries exist in the country, what mineral products they use and need, just how these mineral products are used in each industry and what substitutes could be used instead if secured for a smaller price, I believe we could find a large part of the requisites near at hand and thus save considerable expenditure to the industry. On the other hand, the industries seldom have any idea of what we could do for them, for they generally know little or nothing of geology. To better this situation we need a general clearing-house both for industrial information and for detailed data regarding mineral occurrence.

Professor Jenkins showed many lantern slides of natural phenomena that have been made to serve useful purposes in the growth of the state of Washington.

Virgil R. Kirkham, petroleum geologist of the Department of Geology at the University of Idaho, and assistant geologist for the State Bureau of Mines and Geology, made a brief address, in which he said:

The Idaho Bureau of Mines and Geology has authorized an investigation of all territories in the state that have suffered an acute oil excitement. Competent and conservative petroleum geologists recognize five factors or conditions indispensable to the accumulation of oil or gas in rocks. These are: 1. A source of origin; 2. A reservoir or containing rock; 3. An impervious capping; 4. A suitable structure; 5. A high water saturation. As a result of its official investigations, the Idaho Bureau has concluded that none of the localities of northern Idaho have all of these essential requirements of an oil-producing area.

At Lewiston, Idaho, the elements necessary for the formation of oil are lacking. The well is not drilling in marine sedimentary beds, but in lava flows of basalt. There is absence of a good reservoir rock in basaltic formations. The folds are without closure and are not likely to trap oil were it present.

Farther south along the Snake River, in the neighborhood of Pittsburgh Landing, the situation is essentially the same. The older Permian volcanics appear below the tremendous basalt flows in that area, but do not lend themselves any more favorably to the origin of oil than the latter. Favorable structure is not present at this locality.

In Bonner County, an examination of the geology has proved the rocks to be unfavorable structurally or as reservoir rocks for containing oil. The extreme age of the sedimentary beds, as evidenced by their deformation and metamorphism coupled with lack of fossils, has caused eminent geologists to believe them to have been formed during pre-Cambrian or Cambrian time. Analyses of a large number of gas samples by the U. S. Bureau of Mines and a consideration of the manner of occurrence of the gas in this county has led the State Bureau to conclude that the gas is not from a petroliferous source, but is a marsh gas derived from decaying organic matter buried in the fluviatile deposits.

In summary, I am authorized by Dean Francis A. Thomson, the director of the Bureau, to say that the Bureau of Mines and Geology believes the geology of northern Idaho to be unfavorable for the accumulation of petroleum and natural gas in commercial quantities.

In the week preceding the annual meeting, on Dec. 16, the Columbia Section held a noon meeting at which 20 members were present. J. H. Eby read a short paper on some geologic phenomena in the vicinity of Wardner, Idaho, and showed several maps.

## Affiliated Student Societies

**Miners Club,** University of Arizona, heard an interesting address on oil geology and the possibilities in oil engineering, by Dorsey Hager, on Nov. 30.

**Mining and Metallurgical Society,** Pennsylvania State College, held a meeting early in October, made arrangements for a number of smokers, and elected the following officers: R. B. George, president; W. Davis, vice-president; E. M. Gingerich, secretary-treasurer.

**The Crucible Club,** University of Nevada, has been recognized as an affiliated student society of the A. I. M. E. The members of the club are upper class students of the Mackay School of Mines, University of Nevada, members of the mining faculty and employees of the Reno station of the U. S. Bureau of Mines. Meetings are held monthly. Ernest Harker, president, and James W. Byrkit, Jr., are officers for this year.

**Princeton Engineering Society,** Princeton University, is also a new affiliated student organization. The officers are A. L. Dyer, president; W. F. Dittig, secretary; and F. C. Baselt, treasurer.

**Miners Club,** Oregon State Agricultural College, gave a smoker on Oct. 20. There was no technical program. The Miners Club and the staff of the School of Mines have planned a dinner and smoker at which they will be the hosts of the Oregon Local Section of the Institute.

**Junior Association, Ohio State University.**—At the first meeting of the Junior Association, Professors Nold and Demorest, of the Departments of Mining Engineering and Metallurgy, agreed to dismiss classes for one hour on Friday afternoons for the discussion of topics outside the range of study in the departments. These discussions are to be held by the Junior Association and to be participated in by all. The first topic was "The Relation of the Engineer to Capital and Labor." It was a big success, with much discussion and many new ideas.

The Association held its annual banquet on Nov. 8. Over 40 students, and 10 professors as their guests, enjoyed the evening.

The Association has shown five of the Bureau of Mines moving pictures at its bi-weekly meetings at Lord Hall and has had the pleasure of hearing Doctor Shaw, assistant chief chemist of the Bureau of Mines, speak on the Bureau of Mines.

**Minnesota School of Mines' Society.**—At a recent meeting, F. W. Holler, superintendent of the Surf Inlet mines of the Tonopah Belmont Co., spoke to the Society regarding the exploration and development of these properties. The mine is at Surf Inlet, B. C., 10 mi. from tide water, and when the Tonopah Belmont Co. took an option on the claims about seven years ago, they were confronted with a very serious transportation problem. This was solved by the construction of a concrete dam which furnished a source of power for the generating plant, and backed up the

Digitized by Google

water sufficiently to form a connection between two lakes and provide a water route for barge transport, supplemented by a short rail haul at each end. Mr. Holler also outlined the plan followed in the exploration work, and the development program carried on after a considerable amount of satisfactory ore had been located.

On Nov. 15, Tom Lovering, '22, addressed the Society on the geology of the coastal regions of Newfoundland. Mr. Lovering was a member of a geological reconnaissance party sent to Newfoundland by Yale University in the summer of 1920 to study the Ordovician and the Cambrian, and the general relations of the west coast of Newfoundland and eastern Labrador. He gave a brief description of general conditions, and also described the occurrence of the Wabana iron ores and mining methods at the mines on Isle Royal. W. R. Griswold, '23, spoke briefly on Methods of Sampling of Narrow Vein Deposits.

On Nov. 22, Frank E. Mooney, '23, gave the Society a description of the electrolytic zinc plant of the Anaconda Copper Mining Co. at Great Falls.

On Dec. 1, George Hezzelwood, '23, addressed a Society meeting on Railroad Tunneling in British Columbia. He dealt particularly with an attempt made by the contractors of a Grand Trunk grade construction in 1913 to tunnel through a shoulder of the Selkirk Range in the Fraser River Valley. The course of the tunnel was through loose, unconsolidated materials, mainly clays, and, because of excessive distortion and floor bulge, the project was abandoned when only about 25 per cent completed. The speaker gave a description of some of the obstacles to be expected in soft ground tunneling, and the advisable timbering methods.

**Mining and Geological Society,** Lehigh University, elected its officers for the year 1921–22 at a meeting held on May 19: president, H. C. Beekel, vice-president, E. N. Lamb; secretary, J. M. Newlin; treasurer, B. H. C. Johnson; curators, W. M. Walters and W. M. Glick. The speaker at this meeting was Robert P. Sanborn, manager of the traction department, Edison Storage Battery Co., who spoke on the application of storage batteries to mine haulage.

On Oct. 27, H. A. Reichenbacher gave an interesting talk on pulverized coal and its utilization, illustrated by lantern slides; and on Dec. 1, Dr. J. M. Payne addressed the Society on the subject of Mexico. Doctor Payne showed many views and told many amusing incidents. At the last meeting, J. A. Thomas was elected secretary in place of J. M. Newlin, resigned.

## Woman's Auxiliary

THE regular monthly meeting of the General Council of the W. A. A. I. M E. was held on Thursday, Jan. 5, 1921. There were nine members present. A letter was read from Mrs. Jüssen, provisional director of the Northern California Section, who reported 142 cards of invitation sent out and the formation of a section under way.

Mrs. Philip Wiseman, director of the Southern Californian Section, was present and made an informal report on the activities of this section, which has 62 members. At the monthly luncheons there is usually a talk by a member who has lived in remote mining camps: a relation of her experiences. Recently a member told of her life in Burma, showing native embroideries and curios. This section made, in a month's time, 300 garments for the Red Cross, which were sent to Russia. As a unit of the Needlework Guild of America, this section of the W. A. A. I. M. E. contributed 110 garments last autumn.

The Denver Section reported by letter. A contribution of $182 was sent to the Educational Fund. A committee was appointed, at Thanksgiving time, to receive donations for any engineers who might be in the hospital for tubercular ex-service men.

The Butte Section reported, by letter, the establishment, in July, 1921, of a free kindergarten in the foreign district, three rooms in the school building being provided through the courtesy of the school board. The daily attendance averaged 25. On three mornings in the week a sewing class was held, with 15 girls in attendance. One of the mining companies donated over 100 yards of unbleached muslin for garments. For every dollar donated by individuals to the Community Chest, the mining companies donated a dollar and a half. One committee of this section, headed by Mrs. Norris, calls itself "The Neighbors," and has become a strong factor in Americanization work.

The Anaconda Section made no report.

The Utah Section reported that regular meetings have been held. It is expected that an annual entertainment will be given for the benefit of the Educational Fund, which this section considers "the prime interest of the Auxiliary." The desire of this section is, "that any effort made by it toward local betterment, should, whenever possible, have a bearing on the mining element in the community."

The appointment of Mrs. Jennings as representative of the Washington, D. C. section was confirmed by the Council.

Mrs. Jennings' report, as chairman of the Educational Fund Committee, follows.

CLARE C. REYNDERS,
*Secretary.*

### REPORT OF EXECUTIVE COMMITTEE OF EDUCATIONAL FUND OF W. A. A. I. M. E.

The Executive Committee of the Educational Fund reports that the governing authorities of Columbia University offered to the Directors of the A. I. M. E. the privilege of naming the recipient of a scholarship for the study of mining or metallurgy in the School of Mines, Metallurgy and Chemistry of Columbia Univer-

Digitized by Google

sity, New York, of the value of $350 yearly to cover the cost of tuition.

The Board of Directors of the A. I. M. E. passed a resolution to the effect that the Advisory Board to the Executive Committee of the Educational Fund of the Woman's Auxiliary of the A. I. M. E. be requested to coöperate with the said committee in seeking suitable candidates for appointment, the final choice to be subject to approval by the Board of Directors of the Institute.

In order that this scholarship may more adequately carry out the ideas of the Woman's Auxiliary, the Educational Committee is adding to it the sum of $200 yearly to be granted under the rules for the administration of the Educational Fund, the value of the scholarship being thus raised to $550 per annum.

Letters and notices have been sent to the various sections of the Woman's Auxiliary and to the Student Societies affiliated with the A. I. M. E., inviting applications for the scholarship and stating the requirements and conditions.

Applications must be mailed not later than March 1, with all supplementary and endorsing letters, to Mrs. S. J. Jennings, Chairman of the Educational Fund, 44 East 80th Street, New York City. This mail should be registered. Applications mailed later than March 1 cannot be considered.

The midyear report of the holder of our scholarship to the University of California is most satisfactory.

AMY F. JENNINGS,
*Chairman.*

# Government Papers of Interest to Engineers

## Investigations by the Bureau of Mines*

**Reduction Mills in Western States in 1920.** (Serial No. 2287).—In 1912 an investigation was made by the United States Geological Survey as to the number of reduction mills in the various western states, with details of their equipment, and the results were published in the Mineral Resources report of that year. The present list was compiled by Charles G. Yale, V. C. Heikes, and Chas. W. Henderson of the U. S. Geological Survey, and is being published by the U. S. Bureau of Mines for the benefit of the industry. Strict accuracy in details is not claimed for the present list of reduction mills, as in the limited time at disposal it was not always possible to send for corrections or additional information. The list, however, may be considered a revision of that of 1912.

The list for each state has been bound separately and given a subtitle, and the following are available:

| | | |
|---|---|---|
| Serial | 2287–A | California |
| | 2287–B | Oregon |
| | 2287–C | Washington |
| | 2287–D | Idaho |
| | 2287–E | Utah |
| | 2287–F | Montana |
| | 2287–G | Nevada |
| | 2287–H | Arizona |

**Utilization of Waste Slate as a Filler** (Serial No. 2283). By Oliver Bowles.—All of the information available indicates that waste slate may be used to advantage as a filler in mechanical rubber goods and in some classes of oil-cloths, floor coverings and window shades. Apparently it is not adapted for use in rubber of a grade used in automobile tires. For plastic roofing and flooring products containing coal tar it has long been in use and constitutes a very satisfactory filler.

**Miners' Field Day, Butte, Montana** (Serial No. 2286). By D. Harrington.—In order to stimulate general interest in mine safety among their employees, the mining companies of Butte, Mont., instituted in 1918 a Miners' Field Day, and this field day has since been held annually about the end of July. This paper is an interesting account of the way in which the Miners' Field Day in the Butte district is organized, with data on costs, plan of organization, method of conducting, and the practical benefits derived from it.

**Hot High-nitrogen Gas in a Metal Mine** (Serial No. 2282), By G. E. McElroy.—While investigating the presence of heavy strata gases in certain mines of the East Tintic mining district of Utah, a small, local body of light, very hot gas of high-nitrogen composition was noted in one of the mines. Observations and analyses indicate that this light gas was resulting from very rapid oxidation of finely disseminated pyrite, in lead-silver sulfide ore. The gas was actually mine air that had lost a large proportion of its oxygen content by reaction with the pyrite. This body of gas was hanging in a local high spot about 5 by 5 by 5 ft. in size, caused by caving, at the end of a crosscut. Fifty feet from this spot, an air current of 6000 cu. ft. per min. was entering the 5 by 7 ft. crosscut from a raise from below.

The analyses and the air-free calculations made show that the gas is black damp (defined by Haldane, the English physiologist, as an accumulation of carbon dioxide and nitrogen in proportions larger than those found in atmospheric air) composed almost wholly of nitrogen.

*Reports in full may be obtained from the Director of Bureau of Mines, Washington, D. C. Give serial number.

# Increase of Membership Department

**Total membership as of Dec. 31, 1921, is 10,205**

APPLICATIONS FOR MEMBERSHIP.—The Institute desires to extend its privileges to every person to whom it can be of service. On the other hand, it is not desirable that persons should be admitted to membership in classes for which they are not qualified. Members of the Institute can be of great service if they will make a practice of glancing through the list of applicants and promptly notifying the Committee on Membership, or the Secretary of the Institute, of any person whom they think should not be classified in accordance with the list given.

The following persons have been proposed during the period Dec. 18, 1921 to Jan. 20, 1922, for election as members of the Institute. Their names are published for the information of Members and Associates, from whom the Committee on Membership earnestly invites confidential communications, favorable or unfavorable, concerning these candidates. A sufficient period (varying in the discretion of the Committee, according to the residence of the candidate) will be allowed for the reception of such communications, before any action upon these names by the Committee. After the lapse of this period, the Committee will recommend action by the Board of Directors, which has the power of final election.

## Candidates for Membership

Members

**1—Lawrence Gould Blodgett,** Tulsa, Okla.
Present position—1919 to date: Manager, Operating Department, H. F. Wilcox Oil & Gas Co.
Proposers: J. W. Merritt, James H. Hance, U. S. Grant.

**2—John Briscoe Brown,** Puerto Mexico, Ver., Mexico.
Present position—1920 to date: Scout, Geological Department, Transcontinental Petroleum Co.
Proposers: Joseph T. Singewald, Jr., William A. Baker, Jr., Max W. Ball.

**3—Barnabas Bryan,** Brooklyn, N. Y.
Present position: Associated with Ralph Arnold, New York, N. Y.
Proposers: Carl B. Anderson, Lucius W. Mayer, Eugene H. Dawson.

**4—Robert C. Coffey,** Kirkland Lake, Ontario, Canada.
Present position—1918 to date: Manager, Lake Shore Mines, Ltd.
Proposers: Walter E. Hurd, Percy E. Barbour, Arthur W. Jenks.

**5—Llewellyn Dana Davenport,** Duluth, Minn.
Present position: Consulting Engineer.
Proposers: W. R. Appleby, W. H. Emmons, Frank Hutchinson.

**6—Charles Hollister Davis,** Cheshire, Conn.
Present position—1919 to date: In charge of Waterbury Laboratory of the American Brass Co., Waterbury, Conn.
Proposers: W. H. Bassett, J. C. Bradley, F. G. Smith.

**7—Elmer Harrison Finch,** Monrovia, Cal.
Present position—1920 to date: Geologist, Matador Petroleum Co., Cheyenne, Wyoming.
Proposers: Justus H. Cline, E. F. Davis, Max W. Ball.

**8—Jesse Garrett Gilley,** Pikeville, Ky.
Present position—1920 to date: Chief Engineer, C. G. Evans, Consulting Civil and Mining Engineer.
Proposers: A. J. Baldwin, Charles E. Krebs, J. M. Clark.

**9—Patrick A. Grady,** Huntington, W. Va.
Present position: Consulting Engineer, J. C. Sullivan's Interests, Tralee, W. Va.
Proposers: Charles E. Krebs, J. M. Clark, Ernest M. Merrill.

**10—Roy Jack Grissom,** Pulacayo, Bolivia.
Present position: Mine Superintendent, Cia. Huanchaca de Bolivia.
Proposers: C. Leonard Ball, Charles A. Mitke, John M. Sully.

**11—Edward Patterson Hall,** Phillipsdale, R. I.
Present position—1919 to date: Metallurgist, American Electrical Works.
Proposers: Daniel Boyd, Augustus H. Eustis, F. A. Eustis.

**12—George Martin Hall,** Baltimore, Md.
Present position—1921 to date: Assistant Geologist, United States Geological Survey, in charge of underground water resource work in South Central Montana.
Proposers: Joseph T. Singewald, Jr., Edward B. Mathews, Joseph K. Roberts.

**13—Herbert Brinley Husband,** Dorothy, W. Va.
Present position: Chief Mining Engineer, Chesapeake & Ohio Railway Co., Fuel Mine Operations.
Proposers: R. C. Cofer, E. L. Colcord, L. A. Gates.

**14—William Albert McCullough,** Cleveland, Ohio.
Present position: Mining Engineer on Staff of Crowell & Murray.
Proposers: C. B. Murray, Herbert M. Boylston, L. E. Dunham.

**15—John S. McKeever,** Longacre, W. Va.
Present position—1916 to date: General Superintendent, Kanawha & Hocking Coal & Coke Co.
Proposers: Charles E. Krebs, J. M. Clark, Ernest M. Merrill.

**16—Thomas George Madgwick,** Birmingham, England.
Present position—Professor of Petroleum Technology, Birmingham University.
Proposers: John Cadman, Edwin Ludlow, F. F. Sharpless.

**17—Vincent T. Malcolm,** Indian Orchard, Mass.
Present position: Metallurgist in charge, Chapman Valve Mfg. Co.
Proposers: W. M. Corse, Robert F. Wood, F. P. Gilligan.

**18—Alfred Blake Maury,** New York, N. Y.
Present position—1921 to date: Sales Engineer, Herreshoff Furnace Department, General Chemical Co., and Designing Engineer.
Proposers: Robert H. Cromwell, H. V. Smythe, Louis deB. Lovett.

**19—Walter Millwater,** Arboretum, Worcester, England.
Present position—1920 to date: Manager of Sengie Ayan Tine Mine, Trenggame, Malaya.
Proposers: James Thame, J. F. Mitchell-Roberts, R. O. Stokes.

**20—Charles Riggs Morris,** Virginia City, Nev.
Present position—1917 to date: Mill Superintendent, Mexican Milling Co.
Proposers: S. H. Ball, Alexander Wise, R. A. Hardy.

**21—George Howard Pratt,** Los Angeles, Cal.
Present position—1912 to date: Conducting own assay office.
Proposers: Arthur B. Maxwell, S. Paul Lindau, Edward D. Lynton.

**22—Frank W. Reeves,** Fort Worth, Texas.
Present position—1919 to date: Consulting Geologist and Engineer.
Proposers: D. M. Folsom, Wallace E. Pratt, Carlton Meredith.

**23—Oliver H. Runk,** Mexico, Ky.
Present position—1918 to date: Superintendent, Haffaw Mine for Aluminum Ore Co. of East St. Louis.
Proposers: C. W. Haynes, A. H. Reed, Blakeslee Barnes.

**24—Harry Schagrin,** South Charleston, W. Va.
Present position—1920 to date: Chief Chemist, U. S. Naval Ordnance Plant.
Proposers: Walter H. White, W. J. Priestley, Frank T. Sisco.

Digitized by Google

**25—Henry Seidler,** New York, N. Y.
Present position: With Purchasing Department, Cerro de Pasco Copper Corpn.
Proposers: E. E. Thum, J. W. Mercer, Marshall S. Walker.

**26—Arthur Percival Tanberg,** Henry Clay, Del.
Present position—1920 to date: Director, Experimental Station, E. I. duPont deNemours & Co.
Proposers: W. C. Spruance, Hamilton Bradshaw, Frank S. MacGregor, G. B. Street.

**27—Richard Henry Thomas,** Orange, N. J.
Present position—1913 to date: Superintendent, Bay Plant, Copper Department, Balbach Smelting & Refining Co., Newark, N. J.
Proposers: E. E. Dieffenbach, R. von Seyfried, R. A. Bingham.

**28—Frederick William Trezise,** Appleton, Wis.
Present position: In charge Engineering Instruction, Lawrence College.
Proposers: Rufus M. Bagg, Harold O. Davidson, Thomas W. Orbison.

**29—Jitaro Yonezawa,** New York, N. Y.
Present position—1911 to date: Professor of Mining, The Osaka Higher Technical School, Japan.
Proposers: Shidzuo Komuro, Tatsuro Otagawa, Kenroku Ide.

Associates

**30—Henry Ernest Brauer,** Palmerton, Pa.
Present position—1921 to date: Metallographic Investigator in Metal Sections of the Research Division of the New Jersey Zinc Co.
Proposers: W. M. Peirce, William H. Finkeldey, W. C. Harpster.

**31—William Joseph O'Toole,** Welch, W. Va.
Present position—1920 to date: Vice-President and Manager of Sales, Central Pocahontas Coal Co.
Proposers: Charles E. Krebs, J. M. Clark, Ernest M. Merrill.

**32—Edward E. Thalmann,** Ardsley-on-Hudson, N. Y.
Present position—1919 to date: Bates Iron Co., Assistant to the President; Florence Iron Co., Assistant to the Vice-President. At present—General Briquetting Co., Vice-President and Assistant Treasurer; Ohio Metal Briquetting Co., Treasurer; Schermuly Polarisator Corpn., Vice-President; New York Pyrites Co., Vice-President.
Proposers: F. T. Rubidge, Albert L. Stillman, R. M. Atwater, Jr.

**33—William Joseph Thompson,** Bethlehem, Pa.
Present position—1919 to date: Secretary, Anthracite Coal Operators Assn., Philadelphia, Pa.
Proposers: E. W. Parker, A. H. Armstrong, Alan C. Dodson.

Junior Associates

**34—Benjamin Adelstein,** Butte, Mont.
Student, Montana State School of Mines.
Proposers: Earl B. Young, Theodore Simons, H. T. Mann.

**35—Hermann Charles Beeckel,** Philadelphia, Pa.
Student, Lehigh University, Bethlehem, Pa.
Proposers: Howard Eckfeldt, Benjamin L. Miller, H. B. Pulsifer.

**36—Lester Farragut Bishop,** Butte, Mont.
Student, Montana State School of Mines.
Proposers: Theodore Simons, E. B. Young, H. T. Mann.

**37—Alex. Grove Brockway,** Butte, Mont.
Student, Montana State School of Mines.
Proposers: H. T. Mann, Earl B. Young, Theodore Simons.

**38—Carl Frank Buchner,** Madison, Wis.
Student, University of Wisconsin.
Proposers: E. R. Shorey, Richard S. McCaffery, A. N. Winchell.

**39—Walker Bryson Carroll,** Butte, Mont.
Student, Montana State School of Mines.
Proposers: H. T. Mann, Theodore Simons, A. E. Adami.

**40—Alvis F. Denison,** Cushman, Ark.
Student, Missouri School of Mines.
Proposers: C. R. Forbes, J. R. Guiteras, C. L. Dake.

**41—Thomas Chadbourne Denton,** Cambridge, Mass.
Student, Harvard Engineering School.
Proposers: H. L. Smyth, Albert Sauveur, L. C. Graton.

**42—George Fanta,** Cleveland, Ohio.
Student, Case School of Applied Science.
Proposers: Anthony Jenkin, Kenneth H. Donaldson, H. M. Boylston.

**43—Howard Chandler Fleck,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: C. R. Forbes, C. L. Dake, J. R. Guiteras.

**44—Emil Gustav Hanson,** Socorro, New Mex.
Student, New Mexico State School of Mines.
Proposers: W. G. Ramlow, T. W. Quayle, Cony T. Brown.

**45—Lorin Lindley Hawes,** Socorro, New Mex.
Student, New Mexico State School of Mines.
Proposers: W. G. Ramlow, T. W. Quayle, Cony T. Brown.

**46—Henry G. Hubbard,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: C. R. Forbes, C. L. Dake, J. R. Guiteras.

**47—F. K. Middleton Hunter,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: C. R. Forbes, J. R. Guiteras, C. L. Dake.

**48—Paul Lewis Keller,** State College, Pa.
Student, Pennsylvania State College.
Proposers: E. S. Moore, C. A. Bonine, William R. Chedsey.

**49—Gerald Maitland Kenvair, Jr.,** Butte, Mont.
Student, Montana State School of Mines.
Proposers: H. T. Mann, Earl B. Young, Theodore Simons.

**50—Irwin Wikon Keyes,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: C. R. Forbes, C. L. Dake, J. R. Guiteras.

**51—Kenneth Knight Laudes,** Cambridge, Mass.
Student, Harvard University.
Proposers: H. L. Smyth, Alfred Wandke, L. C. Graton.

**52—Robert Carl Lentz,** Madison, Wis.
Student, University of Wisconsin.
Proposers: E. R. Shorey, Richard S. McCaffery, A. N. Winchell.

**53—Ramon Gregorio Marquez,** Madison, Wis.
Student, University of Wisconsin.
Proposers: E. R. Shorey, Richard S. McCaffery, A. N. Winchell.

**54—Richard Moldenke, Jr.,** Watchung, N. J.
Student, Columbia University.
Proposers: James F. Kemp, Charles P. Berkey, R. J. Colony.

**55—Raymond Edward Murphy,** Rolla, Mo.
Student, Missouri School of Mines and Metallurgy.
Proposers: C. R. Forbes, J. R. Guiteras, C. L. Dake.

**56—Lanfear Barbey Norrie,** Cambridge, Mass.
Student, Harvard Engineering School.
Proposers: H. L. Smyth, G. S. Raymer, L. C. Graton.

**57—John Alfred Potter, Jr.,** Stanford University, Cal.
Graduate Student, Stanford University.
Proposers: W. F. Dietrich, W. H. Shockley, Welton J. Crook.

**58—Bruno Rixleben,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: C. R. Forbes, Joseph R. Guiteras, C. L. Dake.

**59—Edwin A. Thomas,** New York, N. Y.
Student, Columbia University.
Proposers: E. S. Moore, D. F. McFarland, William R. Chedsey.

**60—Edward Torrence, Jr.,** Rolla, Mo.
Student, Missouri School of Mines and Metallurgy.
Proposers: C. R. Forbes, J. R. Guiteras, C. L. Dake.

**61—Leonard Oliver Walde,** Butte, Mont.
Student, Montana State School of Mines.
Proposers: H. T. Mann, E. B. Young, A. E. Adami.

**62—George Andrews Warner,** Socorro, N. Mex.
Student, New Mexico State School of Mines.
Proposers: W. G. Ramlow, T. W. Quayle, Cony T. Brown.

**63—Donald Boardman Weir,** Pullman, Wash.
Student, Washington State College.
Proposers: L. O. Howard, C. G. Warfel, L. K. Armstrong.

**64—Frederick William Wiegand,** Boston, Mass.
Student, Massachusetts Institute of Technology.
Proposers: Charles E. Locke, W. Lindgren, Carle R. Hayward.

**65—Joseph Frank Wosehutz,** Madison, Wis.
Student, University of Wisconsin.
Proposers: E. R. Shorey, Richard S. McCaffery, A. N. Winchell.

**66—Arthur John Yahn,** Madison, Wis.
Student, University of Wisconsin.
Proposers: Richard S. McCaffery, Edward R. Shorey, A. N. Winchell.

Change of Status—Associate to Member

**67—Samuel Jefferson Caudill,** Tulsa, Okla.
Present position—1920 to date: Consulting Geologist and Petroleum Engineer.
Proposers: George C. Matson, Alf. G. Heggem, James H. Gardner.

Digitized by Google

**68—Archie J. McDermid,** Quartzburg, Idaho.
Present position—1920 to date: Mining Engineer, Gold Hill & Iowa Mines Co.
Proposers: Victor J. Lynch, E. E. Carter, E. W. McCullough.

**69—Andrew Nicholls Mackenzie,** Pasadena, Cal.
Present position: Graduate Student, Geology, Stanford University.
Proposers: C. F. Tolman, Jr., W. F. Dietrich, Welton J. Crook.

Change of Status—Junior Associate to Member

**70—Samuel McKirahan,** Rapid City, So. Dak.
Present position—1921 to date: Manager, National Engineering & Refining Co.,
Proposers: F. W. Traphagen, W. C. Bochert, C. C. O'Harra.

# Engineering Societies Library

HARRISON W. CRAVER, Director

## A List of Books on the Electron*

COMPILED BY HARRISON W. CRAVER

This list owes its origin to a suggestion from Professor V. Karapetoff, of Cornell University, that a brief list of references would be useful to students of electrophysics.

It is intended as a guide to some of the more important books on the electron; books from which a correct understanding of present knowlecdge about the nature and properties of electrons may be obtained. No attention has been paid to the numerous important articles that have appeared in periodicals.

Professor Karapetoff and Professor E. Merritt, also of Cornell University, have assisted materially by evaluating the longer list from which selection has been made, and the final list has their approval. Whatever merit it may have is due to their intelligent, helpful criticism.

Abraham, M. "Theorie der Electrisitat." Ed. 3. 1914. Leiprig, Teubner. 10 M.
Allen, H. S. 'Photo-Electricity." 1914. New York, Longmans. $2.10.
Campbell, N. R. "Modern Electrical Theory." Ed. 2. 1914. New York. Putnam. $2.75.
Comstock, D. F. & Troland, L. T. "Nature of Matter and Electricity." 1917. New York, Van Nostrand Co. $2.00.
Cox, John. "Beyond the Atom." 1913. New York, Putnam. $0.40.
Crowther, J. O. "Ions, Electrons and Ionizing Radiations." 1920. New York, Longmans. $4.00.
Cunningham, E. "Relativity, the Electron Theory and Gravitation." Ed. 2. 1921. New York, Longmans. $3.50.
Curtis, H. A. "Electron Theory." 1912. Denver, Colorado Scientific Society.
Fleming, J. A. "Thermionic Valve and its Developments in Radio-Telegraphy and Telephony." 1919. London, Wireless Press. 15s.
Hughes, A. L. "Photo-Electricity." 1914. Cambridge University Press.
Lamor, Joseph. "Aether and Matter." 1920. London.
Lodge, O. J. "Electrons." 1907. New York, MacMillan. $2.00.
Lorentz, H. A. "Theory of Electrons." 1909. New York, G. E. Stechert. $2.50.
Millikan, R. A. "The Electron." 1917. Chicago, University of Chicago Press. $1.50.
Perrin, J. B. "Atoms." 1917. New York, Van Nostrand. $2.50.
Ramsay, William. "Elements and Electrons." 1912. New York, Harper. $0.75.
Richardson, O. W. "Electron Theory of Matter." Ed. 2. 1916. New York, Putnam. $4.50.
—— "Emission of Electricity from Hot Bodies." 1916. New York, Longmans. $2.75.
Rutherford, Ernest. "Constitution of Matter and the Evolution of the Elements." 1916. Washington, Smithsonian Institution. Free.
—— "Radioactive Substances." 1913. New York, Putnam. $4.50.
Soddy, Frederick. "Interpretation of Radium." Ed. 4. 1920. New York, Putnam. $3.75.
—— "Matter and Energy." 1912. New York, Holt. $0.75.
Thomson, J. J. "Conduction of Electricity Through Gases." Ed. 2. 1906. New York, Putnam. $4.00.
—— "Corpuscular Theory of Matter." 1907. New York, Scribner. $2.00.
Townsend, J. S. "Electricity in Gases." 1915. New York, Oxford University Press. $4.75.

*Reprinted from the *Journal* of the American Institute of Electrical Engineers (January, 1922).

## Book Notices

**Automobile Engineering.** Chicago, American Technical Society, 1920. 6 vols., illus., 8 × 6 in., fabrikoid, $29.80.

A course for self-instruction and a book of reference covering the maintenance and operation of automobiles of all kinds. Information is presented clearly and without mathematics, and is illustrated by many cuts and drawings. Earlier editions were entitled "Cyclopedia of Automobile Engineering."

**Bleaching.** By J. Merritt Matthews. N. Y., Chemical Catalog Co., Inc., 1921. 676 pp., illus., 9 × 6 in., cloth, $8.

The author has attempted to give the main facts relating to the bleaching of a variety of materials, and to discuss these facts from the practical point of view of the textile chemist and the actual operative in the mill. The greater part of the book deals with the bleaching of textiles, but other vegetable fibers and materials, such as straw, leather and bone, are also discussed.

**Compteurs de Vapeurs.** By E. Hoehn. Paris, Ch. Béranger 1921. 34 pp., illus., 9 × 6 in., paper, 2 fr.

This pamphlet by the chief engineer of the Swiss association of boiler owners describes the theory and operation of ordinary and recording steam meters, and notes the advantages and disadvantages of the different types.

**Cours de Mécanique Rationelle.** By Louis Roy. Paris. Gauthier-Villars et Cie, 1921. 259 pp., 10 × 6 in., paper,

This volume and the author's previous book on graphic statics and strength of materials form a course of instruction in mechanics for students of engineering. The present work is for beginners and is confined to the elements of mechanics, which it presents so that students will have the grounding necessary for the study of applied mechanics, general physics and electrical engineering.

**Detailed Report on Nicholas County.** By David B. Reger. West Virginia Geological Survey, P. O. Box 848, Morgantown, W. Va. 847 pp. + xx pp. introductory matter. 34 half-tone plates and 22 zinc etchings in text, accompanied by a separate case of topographic and geologic maps. Price, including case of maps, delivery charges paid by the Survey, $3. Extra copies of topographic map, $0.75; of the geologic map, $1.

Nicholas County contains the New River Coal Group, the Kanawha Group and the lower members of the Allegheny series in its northern portion. This report contains a chapter on the paleontology of Nicholas County and a short description of the chert deposits of West Virginia by Dr. W. Armstrong Price.

**Economics of Petroleum.** By Joseph E. Pogue. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 375 pp., plates, illus., 9 × 6 in., cloth, $6.

The purpose of this book is to present the more important economic facts relating to petroleum, to interpret the changes taking place in the industry and to forecast the future trend of these changes. It contains useful information on our resources, the trend of development, production and refining, transportation, prices, trend of consumption, and similar topics.

**Elementary Chemical Microscopy.** By Émile Monnin Chamot. Second edition, partly rewritten and enlarged. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 479 pp., illus., 9 × 6 in., cloth, $4.25.

Intended as an introduction to the microscope and its accessories as tools for the chemist, and as a basis for advanced work in specific fields.

Digitized by Google

**Elements of Illuminating Engineering.** By A. P. Trotter. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Technical primers.) 103 pp., illus., 6 × 4 in., cloth, $0.85.

An introduction to the elements of the subject which gives a clear concise account of theoretical principles and of modern practice in distribution and measurement of illumination.

**Emission of Electricity from Hot Bodies.** By O. W. Richardson. Second edition. Lond. and N. Y., Longmans, Green and Co., 1921. (Monographs on physics.) 320 pp., 9 × 6 in., cloth, $5.25.

One of a series of monographs in physics edited by Sir J. J. Thomson and Professor Horton, revised and enlarged. Deals with emission of positive and negative electricity from hot bodies. The author was one of the first investigators of this subject. A clear, up-to-date account written by one who appreciates fully the experimental difficulties and the adequacy of the theories proposed.

**Essai Philosophique sur les Probabilités.** By Pierre-Simon Laplace. Paris, Gauthier-Villars et Cie, 1921. (Maîtres de la pensée scientifique.) 2 vol., 7 × 4 in., paper, 3 fr. per vol.

In this famous book Laplace presented, without resorting to analysis, the principles and general results of the theory of probabilities, and applied them to some of the most important questions of life. The present edition reproduces the best text in a cheap, convenient edition.

**Files and Filing.** By Ch. Fremont, translated under the supervision of George Taylor. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1920. 148 pp., illus., 11 × 9 in., cloth, $7.50.

A brief readable account of the origin and evolution of the file from the earliest times to modern days, the origin of file-cutting machines, methods of filing and influence of various factors on efficiency, the cut of files, their use and the methods of testing. The technical sections include the results of much scientific investigation in the author's laboratory. Will be interesting not only to makers and users of files, but to students of the history of machines. Fully illustrated.

**Fire Prevention and Fire Protection as Applied to Building Construction.** By Joseph Kendall Freitag. Second edition revised. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 1038 pp., illus., 7 × 4 in., fabrikoid, $5.

Extensively revised; changes in design, construction and equipment approved during the nine years that have elapsed since the first edition have been included.

**Food Products.** By E. H. S. Bailey. Second revised edition. Phila., P. Blakiston's Son & Co., 1921. 55 pp., illus., 8 × 5 in., cloth, $2.50.

Professor Bailey has collected the material distributed through a multitude of books and scientific reports upon the important foods and beverages of the world, their sources, methods of preparation for market, packing, preserving and shipping, composition, nutrient and dietetic value and their use.

**Graphical Analysis; a Text-book on Graphic Statics.** By William S. Wolfe. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 374 pp., illus., 9 × 6 in., cloth, $4.

Based on the author's courses in the University of Illinois. Deals with the analysis of stresses rather than with design or computation of loads, but includes some consideration of these questions also.

**Industrial Hydrogen.** By Hugh S. Taylor. N. Y., Chemical Catalog Co., Inc., 1921. (American Chemical Society. Monograph series.) 210 pp., illus., 9 × 6 in., cloth, $3.50.

Outlines the fundamental principles and essential chemical facts of the industry of hydrogen production, tracing the steps by which the present status has been reached, describing that status in detail and indicating probable future developments. While the chemical problems have been emphasized, the data needed by the engineer in plant design are also present.

**La Loi de Newton est La Loi Unique.** By Max Franck. Paris, Gauthier-Villars et Cie, 1921. 158 pp., 10 × 6 in., paper, 12.50 fr.

The question considered in this book is whether it is possible, with our present knowledge, to formulate the law governing the mechanism of the universe. Upon two postulates, that all potential energy resides in the absolute space of the physicist, and that all matter is formed of an element of inertia movable in space, the author erects a hypothesis, and compares its consequences with known facts, to determine how nearly the two agree. The first consequence is the confirmation of Newton's law which is the reason for the title. The author's theory uses only the notions of space, time, force and inertia admitted in Euclidean geometry and mechanics.

**Manual of Determinative Mineralogy.** By J. Volney Lewis Third revised and enlarged edition. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 298 pp., tables, 9 × 6 in., cloth, $3.

The blowpipe tables have been thoroughly revised and recast, and a new classification of minerals based on their physical properties has been added. The blowpipe tables include about 355 minerals and the physical classification about 290. The physical classification differs from common practice by eliminating luster as a basis of classification. The book is for the geologist and engineer, as well as for the student.

**Market Analysis.** By Percival White. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 340 pp., illus., 8 × 6 in., cloth. $3.50.

A guide for manufacturers, sales managers, engineers and others interested in the analysis and organization of markets. Gives instructions for conducting a market survey.

**Material Handling Cyclopedia.** Compiled and edited by Roy V Wright, John G. Little and Robert C. Augur. N. Y., Simmons-Boardman Publishing Co., 1921 846 pp., illus., 12 × 9 in., cloth, $10.

Definitions, descriptions, illustrations, applications and methods of operation of industrial devices for handling materials. Covers hoisting machinery, package conveyors, loose material conveyors, elevators, trackless transportation, industrial rail transportation and handling systems. Each section has been prepared by a specialist.

**Mémoires sur l'Électromagnétisme et l'Électrodynamique.** By André-Marie Ampère. 110 pp., illus., 7 × 4 in., paper, 3 fr.

In these two classic memoirs Ampère described his experiments upon the action exerted on an electric current by another current or a magnet; also the results of his study of the formula expressing the attraction and repulsion between two infinitely small elements of two conductors.

**Die Naturlichen und Kunstlichen Asphalte.** By J. Narcusson. Leipzig, Wilhelm, Engelmann. 262 pp., illus., 9 × 6 in., cloth, 34 M.

The first section discusses the occurrence, composition, properties and uses of asphalt, tars and pitches, and gives methods for their physical and chemical examination. Section two treats of asphalt products, sheet asphalt, asphalt cements, roofing papers, insulating materials, paints, etc., and pays special attention to methods for testing them. A list of the more important German, French and British patents is included. The book is based on investigations at the National Testing Laboratory. The methods of testing have given satisfaction during long use.

**La Physique Théorique Nouvelle.** By Julien Pacotte. Paris, Gauthier-Villars et Cie, 1921. 182 pp., 10 × 6 in., paper, 12 fr.

The new physics in question had its origin in Lorentz's electrodynamics, which is the definitive form of Maxwell's theory; its most advanced theories are due to Einstein; it has to do with relativity, with the energy equivalent of two masses of matter, with atoms of energy.

The author presents a historical, critical, non-mathematical account of the theories that underlie modern ideas.

**Practical Least Squares.** By Ora Miner Leland. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 237 pp., 9 × 6 in., cloth, $3.

A textbook based on the course given to students of civil engineering at Cornell University, designed particularly for short courses of instruction and for engineers and scientists in private practice. It will not replace more elaborate treatises, but the author hopes it will introduce the student directly to the simpler methods of solving the ordinary problems in adjustment.

**Public Opinion and the Steel Strike.** Supplementary reports of the investigators to the Commission of Inquiry, the Interchurch World Movement. N. Y., Harcourt, Brace and Co., 1921. 346 pp., 8 × 6 in., cloth, $2.50.

This volume contains over half the supplementary reports, published not only as supporting documents to the Report on the Steel Strike of 1919, but also as separate fuller studies of special phases of the investigation.

**Radio Questions and Answers.** By Arthur R. Nilson First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 86 pp., illus., 7 × 5 in., boards, $1.

A quiz compend for those preparing for examination. Treats of theory, apparatus, laws and regulations, etc.

**Radioactivity and Radioactive Substances.** By J. Chadwick. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Technical primers.) 111 pp., illus., 6 × 4 in., cloth, $0.85.

A simple, concise, accurate introduction to the subject of radioactive phenomena, by one with first-hand knowledge of the facts.

Digitized by Google

**Railroads of Mexico.** By Fred Wilbur Powell. Boston, Stratford Co., 1921. 226 pp., 8 × 5 in., cloth, $2.

The author has endeavored to fill the lack of authentic information on the Mexican railroad situation by a study of the fragmentary data available. The first section of the book contains an account of transportation during the period following the Diaz régime and of the situation today. Part two is a summary of the development of the great Mexican system of land transportation. Part three presents the author's conclusions. An extensive bibliography is given.

**Taschenbuch für Bauingenieure.** By Max Foerster. Vierte auflage. Berlin, Julius Springer, 1921. 2 vol, illus., diagrs., tables, 8 × 5 in., cloth.

The field covered includes construction of public works, buildings, bridges, railroads and machinery. Prepared by specialists, under Dr. Foerster's guidance. Four editions within ten years.

**Treatise on the Integral Calculus.** By Joseph Edwards. Vol. 1. Lond., Macmillan and Co., Ltd., 1921. 907 pp., 9 × 6 in., cloth, $16. (Gift of The Macmillan Co., N. Y.)

The first volume of an extensive treatise for advanced students. Intended to give the reader a good working knowledge of integral calculus, practical and theoretical, as clearly as possible, with abundance of illustrative examples and instances of the application of the principles explained.

**Turbines.** By A. E. Tompkins. Third edition, revised. Lond., Society for Promoting Christian Knowledge; N. Y., The Macmillan Co., 1921. 180 pp., illus., 8 × 5 in., cloth, $2.50.

In simple, non-mathematical fashion, describes good modern practice in the construction and working arrangement of water turbines, turbine pumps and steam turbines. Useful to students and to men engaged in fitting and repairing turbines.

**Vorrichtungen im Maschinenbau Nebst Anwendungsbeispielen.** By Otto Lich. Berlin, Julius Springer, 1921. 507 pp., illus., diagrs., 9 × 6 in., cloth, 120 M.

A detailed study of clamps, fixtures and jigs for machine tools and of their application to increase output. All the customary operations, boring, slotting, planing, milling, forging, hardening, etc., are considered. There is also a section on the savings obtainable by such attachments and one on maintenance and repair. For machine builders, and for operators who wish to increase the efficiency of existing equipment. The author presents his book as a contribution to the reconstruction of the German metal industries, which he believes will be possible only through the greatest possible economy of time and labor.

# Employment Service Bureau

Notices for this column are not acknowledged by letter. Notices received before the 15th of the month will appear in the next issue.

Correspondence relating to replies to advertisements returned to the Employment Bureau will be held in the Bureau for one month.

Positions of the Bureau are on file in the offices of the member societies of the Federated American Engineering Societies and with secretaries of A. I. M. E. local sections.

## Engineers Available

**Chemical Executive.**—Ten years in South America. Assistant manager large enterprise employing 800 men in mining, milling and maintenance. Fitted by experience and ability to handle native labor, and knowledge of customs and language for executive position in chemical or mining and milling capacity. IM–1526.

**Mechanical Engineer.**—Twenty years with leading copper and steel companies on maintenance and construction. Will consider chief draftsmanship at large plant. Just finishing 6-year foreign contract. States preferred. IM–1527.

**Manager or Superintendent.**—Technical graduate. Seventeen years in development and operation of mining properties. Ten years with one of largest companies in Mexico. Age 40. Married. IM–1528.

**Master Mechanic.**—Twenty years experience master mechanic on mines (both underground and steam-shovel mining), smelters, shops, foundry and locomotives. Married. Age 49. IM–1529.

**Mining and Mechanical Executive.**—University instructor or editorial engagement; North or West preferred. Technical (Lehigh University) graduate, 22 years practical experience engineering, managerial, vocational instructor and editorial work with large corporation. Age 44. Married, with family. IM–1530.

**Metallurgical Engineer.**—Capable and experienced in heat treatment and mechanical treatment of iron, steel, and non-ferrous alloys; also in conducting and directing research along these lines. IM–1531.

**Superintendent or Chief Engineer.**—Experience as chief draftsman, chief engineer and superintendent on construction and operation, smelters, electrolytic plants and general construction. Age 40. Married. IM–1532.

**Mining Engineer.**—Varied experience, particularly in copper and non-metallic industries. Prefers examination, report, or other technical position rather than strictly administrative or operating work. Somewhat familiar with Central and South America. Appointment in New York or other eastern locality. IM–1533.

**Geologist and Engineer.**—Experienced in geological explorations and detailed mine examinations in B. C. and Mexico. Speaks Spanish. IM–1534.

**Mine Manager or Superintendent.**—Twenty years experience, technical, practical and executive, principally metal mining. Some field and office work. Familiar milling and flotation. Foreign experience. Married. Available on short notice. IM–1535.

**Quarry and Open-cut Operator.**—Has made specialty of surface mining of large orebodies, big tonnages and low unit costs. College man, 39 years of age, married. Eight years experience in U. S. and seven in Mexico, in gold, silver-lead and copper properties, underground, surface operations, construction, efficiency and cost analysis. Engaged in Mexico but wishes to change. Fluent Spanish. IM–1536.

**Metallurgical Engineer.**—Harvard, M. I. T., graduate, 29 years of age, desires executive, technical, or sales connection. Experience: melter on Heroult electric furnace, making carbon and alloy steel castings; metallurgist and chemist for large steel plant; metallurgical engineer for carbon and high-speed steel tool manufacturing concern, in charge of chemical, metallurgical testing laboratories and heat treatment departments; metallurgical engineer for automobile drop forging manufacturing

Digitized by Google

concern, in charge of metallurgical laboratory, heat treatment department, crucible steel and brass, bronze, aluminum foundry; works manager and secretary-treasurer of company manufacturing high-speed and other alloy steel tools by new process. IM–1537.

## Positions Open

**Transmission Line Superintendent.**—Must be conversant with practice in transmission lines, 100,000 volt, three-phase, 50-cycle. Capable of taking entire charge of transmission system of approximately 400 miles of line; familiar with construction and operating work, and capable of handling native help. Reply stating age, experience, training and salary desired. India. X–1292.

**Engineer** to take charge of an electrolytic silver refinery. Mass. X–1314.

**Expert Metallurgical Engineer** with experience in electrolytic partition of gold and silver. South America. X–1449.

**Salesmen.**—Two technical men who have had underground metal-mining experience, and who are between the ages of 25 and 35. Headquarters Butte, Mont. and Phoenix, Ariz. X–1475.

**Engineer** with practical converter experience in metallurgy of copper. Apply by letter stating age, education and experience. New Jersey. X–1529.

**Engineer** to sell preferred shares of public utilities. Must have had this experience. Single man 30 to 40 years old preferred. Willing to locate in small western cities for short periods. Apply by letter stating age, education and experience. X–1546.

**Expert Die-casting Engineer** for production work. Good personality and executive experience. Only men with die-casting experience considered. V–13.

**Search Assistants** educated in physics and electrical engineering. Recent graduates. East Pittsburgh. Apply by letter. V–33.

**Engineer** to assist in promoting drainage projects in places where they will accomplish a maximum reduction in the prevalence of malaria. Able to pass upon engineering features of drainage project and determine whether it would be feasible and advisable from a financial standpoint, whether it would eliminate malaria within the area, and to see that work would not increase malaria. So. Carolina. V–34.

**Engineer** to work with head chemist, principally on paints, oils and varnishes. Chemical engineer preferred. Mass. V–35.

**Fuel Engineer.**—Well acquainted with burning of cement, able to make determination on economical fuel consumption in kilns, etc. Apply by letter. Pennsylvania. V–41.

**Chemist.**—Technical education and actual experience, as assistant in laboratory of refinery. Indiana. V–64.

**Young Engineer** able to handle men and keep costs, with experience in mining and milling white clay. Temporary, but may be permanent for right man. South Carolina. V–80.

**First-class Operating and Manufacturing Engineer** to take charge of work of moving overburden, mining clay, and operating a drying and pulverizing plant. Eastern States. V–92.

# Industrial News and Developments

Devoted to manufacturing and trade news of interest and value to the mining and metallurgical industry and invited from manufacturers and dealers. Scrutinized but not vouched for by the Institute.

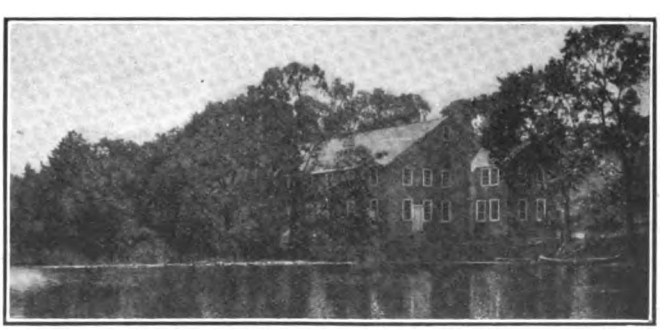
## Testing That Pays Dividends

THAT is the kind of testing for which the Westport Mill of the Dorr Company is intended. When a manufacturer is asked to replace an old and tried machine or method; when a banker or investor is urged to put his dollars behind a new product or a new process; one question instantly presents itself: "Will it pay?"

The idea of laboratories and testing plants in which to carry on the research needed to answer that question is not new, but the Westport Mill is unique in many respects. It is in the country, at Westport, Conn., not far from city conveniences, but far enough for a man to work and think without distraction and with all the inspiration that trees and brooks and good fresh air can bring.

The main building was originally a grist mill, but its interior now contains laboratories for organic and inorganic chemical work and a plant for tests of any process involving crushing, sampling, grinding, roasting, leaching, classification, dewatering, filtering or washing of coarse or finely divided solids. There is ample floor space for the installation of special machines, so that clients may, under certain conditions, conduct their own tests, and there are living quarters at the mill for transient visitors.

A problem submitted to the mill is considered from two aspects: Is it of such a nature that experience will enable the Dorr Company to handle it to the best advantage? Does its solution show genuine promise of profit to those interested in it? If the preliminary study is satisfactory, the problem is turned over to the director of the Westport Mill, with a full report of all conditions surrounding it.



THE WESTPORT MILL, CONTAINING LABORATORIES AND TESTING PLANT OF THE DORR COMPANY.

The mill and its work are described in a 16-page illustrated booklet just issued by the Dorr Company, under the title that heads this article. The company has offices at 101 Park Ave., New York City, in Denver, and in London, England.

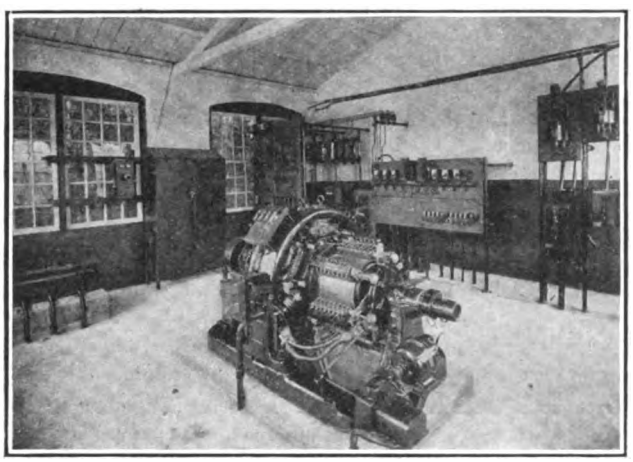
## Automatic Substation Demonstration

THE application of the automatic substation to coal-mining operations was demonstrated on Dec. 7 at the Drifton Colliery near Hazleton, Pa., under the joint auspices of the Lehigh Valley Coal Co. and the General Electric Co. The subject of the demonstration was a 200-kw. synchronous converter and automatic switching equipment operating from a 4600-volt incoming line, delivering direct current at 275 volts. This substation, which is in an isolated place, feeds the direct current to the mine through a bore hole and operates without attendance. It is actuated to start and stop by means of one small manually



INTERIOR VIEW OF AUTOMATIC SUBSTATION.

operated switch in an engine house about ½ mi. away, but all of the switching operations required for starting, stopping and protecting the equipment are automatic within the substation itself.

During the forenoon the purposes and the method of operation of the equipment and its parts were explained and the equipment was stopped and started. After the mine had loaded out, a further demonstration was made, in which abnormal conditions were produced or imitated, to illustrate the protection during emergencies and the automatic resumption of service when conditions return to normal.

Over sixty engineers and superintendents were present.

## Storage-battery Locomotive Approved

THE second official approval of a storage-battery locomotive for use in gaseous mines was issued by the United States Bureau of Mines to the Jeffrey Manufacturing Co., Columbus, Ohio. The approval covers a 6-ton storage-battery locomotive, which may be equipped with a battery consisting of either 80 Type-A-8 Edison cells or 48 Type M.V. 21 plate Iron-Clad Exide cells. Caustic potash is specified as the electrolyte for use with the Edison battery.

Each approved equipment will have an approval plate attached to the controller, bearing the seal of the Department of the Interior, Bureau of Mines, and including a caution statement which should aid both company and state inspectors in keeping the locomotives in a permissible condition.

## Industrial Notes

**W. S. Rockwell Co.**, New York, has appointed Gibbons Bros. Ltd., Dudley, Worc., England, its representative for the British Isles.

**D. T. Eastman,** having resigned as advertising manager of the Eagle-Picher Lead Co., Chicago, announces the organization of Eastman & Co., Technical Advertising, 63 E. Adams St., Chicago, Ill.

**C. G. Young Co., Inc.**, Consulting Engineers, has removed from 501 Fifth Ave., New York City, to the Bankers Trust Company Bldg. at 14 Wall St.

**Combustion Engineering Corpn.**, New York, has opened a branch office at 806 First National Bank Bldg., Pittsburgh, Pa. This office will be in charge of W. C. Stripe, formerly manager of the company's Philadelphia offices.

## Trade Catalogs

**Scovill Mfg. Co.**, Waterbury, Conn.—Tube Facts gives information about the Scovill company and the tubes it manufactures.

**Calorizing Company of Pittsburgh.**—Bulletin CT-1 on Calite castings for use in high temperature.

**Triplex Machine Tool Corpn.**, New York City.—Cat. No. 1, on Triplex No. 1 machine tool.

**Uehling Instrument Co.**, Paterson, N. J.—Bulletin 220, Magnitude of the Power Plant's Chimney Loss.

Bulletin 221, Relation Between $CO_2$ and Money Wasted up the Chimney.

**Pennsylvania Pump & Compressor Co.**, Easton, Pa.—Bulletin 102, on Pennsylvania single-stage, straight-line air compressors and vacuum pumps, both belt- and steam-driven types. This describes the special features, such as plate valves with inlet and discharge valve assembly interchangeable, removable phosphor-bronze main bearings, aluminum oil guard, etc.

**F. Davidson & Co.**, 26 Gt. Portland St., London.—Bulletin describing the Davon Micro-Telescope and Super-Microscope and the various developments thereof. The former is a combination of microscope and telescope, doing the work of both instruments and filling the gap between them. The Super-microscope provides increased depth of focus in the microscope both for visual observations and photomicrography.

The critical image having been obtained, the Super-microscope offers the following advantages in high power microscopy: (1) An increase of nearly 100 per cent. in the magnification usually given by a ⅙-in. objective, enabling it, if of high N. A., to be used for most purposes for which the 1/12-in. oil immersion objective is now used. (2) An increase of 50 per cent. at least on the magnification usually given by a 1/12-in. (3) Variable magnification: from 600 to 1100 with ⅙-in., or to 1500 with 1/12-in. without loss of resolution. These results have been obtained on achromatic objectives, and without either an achromatic condenser or color filter. Using an achromatic condenser and color filter, magnification up to a limit of 1350 can be effectively employed with a ⅙-in. With higher grade objectives such as the semi-apochromatic or fluorite, still better results may be obtained.

## EDITORIAL

### Plea for Conservation of Helium Gas*

THE importance of helium gas, either for national defense or for future use in commercial aerial transportation, is due to its non-inflammable, non-explosive, and inert qualities. It has a lifting power equal to 92 per cent. of that of hydrogen. The cost of its segregation from the natural gases in which it occurs has been reduced from the pre-war figure of $1700 per single cubic foot to less than one ten-thousandth of that figure and a further great reduction is expected.

The recent successful flight of the first helium-filled lighter than air dirigible of the Navy, the C-7, from Norfolk to and around Washington and return, has demonstrated not only the added safety in the flight of such a helium-filled ship, but also remarkable operating advantages. When the time comes for passengers to take passage in a helium-filled airship from New York to San Francisco, for example, safety will be a most important factor and non-inflammable and non-explosive helium instead of hydrogen will be a requirement for such airships.

The United States is the only country whose natural resources, so far as is known, include helium in commercial quantities. The immediate sources available are certain natural gases occurring almost entirely in the United States. But there will be no earnest exploitation of helium unless a speedy and extensive conservation program be carried through either by the government or by financially strong commercial agencies. At the present time it is estimated that there is going to waste annually, through the unconserved and ungoverned use of natural gas in various states, a volume of helium equal to 400,000,000 cu. ft., with a force expressed as balancing power equal to 25,000,000 lb. The program which combines the two problems of conservation and storage, by leaving the gas under ground, is a practical one. This program implies the production of a working amount of helium only.

Digitized by Google

It is not safe to infer that there is ample time for conservation of helium because the natural gas supply is abundant. Helium is found in small percentages in natural gases widely disseminated over the country, it is true, but there are only certain fields in which the percentage is sufficiently high to warrant economical production. Underground conservation, along the same lines adopted by Nature through all the years before science had come to know of the existence of this new and valuable gas, must be restored pending that date when studies now under way succeed in applying the principles of thermo-dynamics and mechanics to the large-scale low-cost production of this gas.

Immediate conservation of the fast diminishing supply is necessary. The supply is all too limited at best. Once gone it cannot be replaced, and the United States is the only country known to contain helium in amounts warranting attempts at commercial exploitation. Enough has been produced to permit aeronautic experimentation to begin, and enough work done to point the way to cheap production.

H. S. MULLIKEN.

This was sent to the printer before the recent disaster to the U. S. dirigible "Roma" at Langley Field.—EDITOR.

## Economic Forecasts

FORECASTS are always uncertain things, but they are made, and have to be made. As soon as mankind emerged from the state of barbarism the direction of affairs passed into the hands of men who were able by their intelligence and reasoning powers to forecast coming events. At the present time every man of business and every engineer is bound to forecast something or other in the course of his daily work. In the highest rank of importance in the determination of the courses of nations and industries is the forecasting of broad economic developments. After they have happened and we look back upon them we see that they were inevitable. But in looking forward the vision is always obscured by mists of the unknown. This is why there are generally differences in opinion.

At present, the most vital concern of the American people, of the people of the whole world, is what is going to happen in 1922. Perhaps there was never a time when forecasts were so widely different. They are as far apart as the north and south poles. It will serve a useful purpose to summarize these opinions and explain the reasons for the differences between them.

According to one opinion, the United States has passed through the worst of the economic readjustment following the war and is now industrially moving upward, with prospect of the early advent of a period of unparalleled industrial prosperity, the arrival of which is expected early in 1922.

According to the other opinion, the United States has passed through only the first stage of the economic readjustment, the consummation of which is still far distant, with the prospect that 1922 will be a year of great trouble.

Popularly, the first is the majority opinion, and the second the minority. There are, of course, intermediate opinions, but they are the expression of conservativeness rather than reflections of fundamental thought.

The bases for the first opinion are these:

1. A theory of business cycles, evincing the idea that business in the aggregate moves in undulations during more or less regular periods and that it is now about time for an upward movement.

2. The unquestionable evidence of a certain increase in the physical volume of business, beginning with the fourth quarter of 1921, or thereabouts.

3. The theory that there will be a secondary period of inflation, as a consequence of the quantity of gold now in the possession of this country and the ability to expand credit upon this basis.

The first of these reasons may be dismissed as unworthy of serious attention. The idea of ups and downs in business is clearly founded upon facts, but that there is any natural law as to regular periodicity is irrational.

The second reason for expecting an early return of prosperity is considerably associated with the first. Because of the thought that the time has arrived for a periodic change, the fact that there has been a certain improvement is accepted as evidence in proof of the theory. This is, however, something on the order of estimating the future earnings of a mine from the records of the past, without taking into consideration the probable conditions in the future.

We can find adequate explanations for the improvement in physical volume of business since Oct. 1, without any self-deception as to what it may mean. Undoubtedly the people of the country have been conducting their affairs for a long time with a subnormal and diminishing stock of goods. The time was bound to come when excessive depletion in certain lines would necessitate a replenishing, just as the individual merchant is constantly obliged to make in evening up. Secondly, there has been some increase in the volume of building, for which there is urgent need, that has been undertaken by some people who have come to the conclusion that even now costs are relatively cheap. Such persons may be right if the third reason for expecting early activity, *viz.*, renewed inflation, is sound.

The bases for the second, or minority, opinion are these:

1. The impoverishment of the world in property and man power.

2. The staggering indebtedness of the nations, external and internal.

3. The chaos in the currencies of Europe.

4. The destruction of all principles of authority, outside of a few countries.

Digitized by Google

5. The unbalance of economic conditions everywhere, including the United States.

These are bold outlines of grave subjects, each of which is big enough for a book. Three years after the armistice scarcely any progress has been made in the readjustment of any of them. It is unforeseen how prosperity can grow in any country in the face of them.

The economists who entertain the second opinion do not consider that in countries like the United States which remained on a gold basis the high prices of 1916–20 were due to currency inflation, but rather were they ascribable to conditions of demand and supply. Expansion in the volume of currency followed the need for it and contraction conformed to the decline in requirements. This is the pronouncement of the Federal Reserve Board.

If, then, there were no currency inflation in 1916–20 there is no reason to expect a secondary inflation in 1922. Money is steadily being released, to be sure, by the liquidation of loans on commodities which are gradually being consumed; and being so released it seeks investment, which is reflected in the rising prices for bonds. It is in prospect that the interest rate will fall to a low point, but it does not necessarily follow from this that money will seek investment immediately in new enterprises. Probably it will not until the readjustment of prices for commodities and wages for labor has become complete, or nearly so.

When that stage has been reached there must necessarily be extensive industrial activity in the United States for the replenishment of depleted stocks of goods and in the building that is required to make good the deficiency in our housing capacity and transportation facilities. This may be regarded as certain, for the need exists and there will be the means after some corrections in our affairs have been made.

The holders of the first opinion, *viz.*, a secondary inflation with its illusory activity, look for a serious collapse later on; at least the more far-sighted of them do. It comes, therefore, to this: One view contemplates early activity followed by depression, while the other sees a prospect of continued depression and readjustment, followed by activity. I think this is a fair statement of the two opposite forecasts and the reasons upon which they are based.

While the general trend of events appears to be probable in one of these directions, so far as can be discerned now, there are likely to be occurrences that will cause complete upsets of any forecast. This is one of the contingencies that endangers forecasting. There are possibilities of this nature that we can imagine; for example, war in Ireland, the declaration of bankruptcy by Germany, the granting of a soldiers' bonus in the United States. Events of that nature may switch world economic affairs upon a new track, without however altering the fundamentals.

## Legal and Academic Definitions of Engineering

WHEN Engineering Council's Committee on Licensing of Engineers early in 1919 began its task of framing a model bill for the purpose of licensing, it seemed desirable to include a definition of engineer and engineering. Many attempts at such definition were made by the committee and A. D. Flinn, secretary of the Council, aided by eminent legal and engineering talent, with the resources of the largest technical library in the world at hand. The result was a 22-page typewritten report of the greatest interest which did not, however, define either word. Not the least interesting part of this report states:

> Many definitions of engineer and engineering were found in dictionaries, encyclopaedias and engineering literature. None proved adequate for the purposes of a statute, for none was found sufficiently comprehensive for the modern profession of engineering which did not also include architecture and possibly other professions of the applied sciences. The Committee on Licensing of Engineers concluded that it was impracticable to write a definition suited to its purposes.

The first New York license law, which was passed in May, 1920, did not contain a definition and the attorney-general of the state ruled that the Board of Education could not license anything it did not define and therefore an amendment must be drawn containing a definition. This definition was drawn by a prominent civil engineer and was predicated on the use of the terms by the Institution of Civil Engineers in England and it was felt that, having more than 100 years usage to support it, it would stand the test of the requirements should it ever be tested in court.

However, the attorney general pronounced it unworkable and said that under it a football coach or the director of a rowing crew could take out a license as a professional engineer because he was directing the forces of nature for human welfare or the public good.

The Engineering Council's illuminating report on this subject tells of the great difficulties of preparing a definition to embrace all branches of engineering and not include other professions or other men who "by an unfortunate duality in the English vocabulary are also called engineers," like engine drivers, motormen, etc. This report of Engineering Council listed 57 different varieties of professional engineers as distinguished from vocational engineers.

In the difficult search for an all embracing definition, Gano Dunn, then president of the A. I. E. E., seeking for that which might be expected to be common to all kinds of engineers, said, "A light is shed if we examine the popular definition that engineering is 'educated common sense.' Can it be that unlike physician, lawyer, teacher, the term engineer does not describe what a man does, but rather how he does it? A method rather than an occupation? It is even so; that is, essentially and with limitations." In summing up his investigations and his arguments he concluded that the profession of engineering, while it may be an occupation "also is a way of thinking and as such is not an occupation but the latest and most highly devel-

Digitized by Google

oped scientific method of solving all kinds of practical problems of matter and force for the benefit of the human race."

It seems evident that no academic definition of engineering has yet been found which is a good working legal definition, and it is equally evident that no legal definition yet produced even approaches satisfaction to the engineering profession.

## National Mine Safety Movement

IT SEEMS to a prejudiced observer like myself that the achievements of the Mining Section of the National Safety Council in the past have been so solid that it deserves the strongest support the mining industry can give to this movement. Also, the possibilities of great benefit accruing to the various members of the Institute, providing they personally and directly contribute to this field of endeavor, warrant their urgent solicitation for an active participation in the safety movement through this body.

It is my impression that very few mining executives of the rank of superintendent or higher have taken the trouble to become so vitally interested in the safety movement as to participate actively in the detail direction of such a movement in their plant or to take up actively such work in any national safety organization which might deal with their problem. If so, this is a great mistake on their part, for safety and efficiency are so closely correlated as to be inseparable. The most efficient method should be the safest practical method; and vice versa, the safest practical method should be the most efficient method. The very fact that increased efficiency reduces the number of units of labor required per unit of production is in itself a reduction of hazard; also, when a workman becomes so trained in the practice of safe methods and his fellow workmen are also careful in the same degree, there is little distracting effort on their part to protect themselves from unknown hazards, and the result is a closer attention to their work and a considerable increase in efficiency.

My visions and hopes for the future of this movement are that 3000 or 4000, instead of 300 or 400 as at present, will participate in furthering this work; that local sections may be organized in the various mining camps and mining centers of the country; and in the third place, it is my hope that the members of the American Institute of Mining and Metallurgical Engineers may be drawn into joint meetings with the Mining Section of the National Safety Council and that it will be possible, therefore, to get the direct attention of a great many mining executives who have so far delegated the consideration of the practical phases of accident prevention work to the safety engineers in their organizations without having themselves clearly recognized the various details that arise.

The safety movement needs the direct contact of such men in the puzzling questions which continually arise in this field of work. These men also need contact with the foremen and shift bosses and safety engineers upon whom the success of this work has largely depended and it is to be hoped that in the joint meetings of the A. I. M. E. there may be brought about a freedom of discussion representative not only of the executive group but of the working and supervisory group of the mining industry. There has been some success in these lines in the meetings of the Mining Section of the National Safety Council and I consider that it has performed a very real benefit to the industry in furnishing a place where foremen and shift bosses, and sometimes miners, have been led to discuss their own intimate problems in the presence of some executives. It seems to me that the Institute very greatly needs this contact of the man nearest in responsibility to the productivity of labor with the executive in discussion of their mutual problems, both, as they refer to the safety movement and also as they touch upon the other interests of the A. I. M. E.

B. F. TILLSON.

## Patient Office Relief Bill Passed

WITHOUT a dissenting vote the Patent Office Relief Bill, after having passed the House, was passed by the Senate and has been signed by the President. This is the culmination of three years persistent and energetic effort on the part of engineers to accomplish this much desired result which is in no way class legislation but is pre-eminently for the good of the entire community. It is an example of the good that can result from engineer participation in other than technical endeavors.

PERCY E. BARBOUR.

## Topographic Appropriation Cut

THE House Appropriations Committee reported the Department of the Interior bill cutting the budget recommendation of $425,000 for topographic mapping work to $275,000. The House voted down an amendment of Representative Hayden of Arizona to increase this appropriation to the budget recommendation of $425,000. Engineers are vitally interested in this item and they hope to convince the Senate Committee that an appropriation of at least $425,000 should be made. Should this topographic mapping work be curtailed to the extent necessary under an appropriation of only $275,000, it would so cripple the state coöperative work and the topographic mapping branch of the Geological Survey that completion of the work would not be in time to benefit the present generation.

# Review of the Month

THE great subject of interest in American affairs during February was the consideration of the proposed soldier bonus. This proposal was based upon the idea that, because most of the workers of the United States had enjoyed high wages during war, the soldiers were entitled to "adjusted compensation" in order to equalize things. It overlooked the fact that the soldiers, themselves, had the opportunity to enjoy high wages in 1919 and 1920, when rates were highest. Apart from this, the whole project was founded on fallacies and involved what would be nothing less than economic crime. Although it looked as if the measure were destined to be railroaded through Congress, so great a storm of protest was pelted upon Congress that the present outlook is that the whole project will be abandoned.

There was probably some increase in the physical volume of business during February. A rise in prices for agricultural products assisted the farmers materially. These developments, however, are not to be construed as presaging any general upward movement.

On the contrary, the current year is to be contemplated as one of serious labor troubles, following inevitable reductions of wages. These began in February in the form of an extensive strike in the cotton textile industry of New England, accompanied by some rioting in Rhode Island. The coal miners have had numerous conferences, without coming to any encouraging results, and the stage appears to be fully set for a general strike beginning Apr. 1. About the only question now is whether this will comprise both the bituminous and anthracite miners. If the latter refuse to go out, no serious shortage of coal is anticipated, the belief being that the existing stocks together with the output of the non-union mines will supply the demand, which is sub-normal even now.

In the metal industries, lead and zinc were dull but stable. The weakening tendency in iron and steel that was manifest during January appeared to be checked, at least temporarily. Copper was characterized by a distinct weakness and a considerable decline in the market. This downward movement was inspired by the news during January that several of the important mining companies were taking steps to resume production. During February the demand for copper, both foreign and domestic, was poor.

As the result of the negotiation whereby the Anaconda Copper Mining Co. was to secure the controlling interest in the American Brass Co., partly for cash and partly for exchange of stock, upward of 149,800 shares of the 150,000 shares of the American Brass Co. were turned into Anaconda. The latter became therefore practically the sole owner of the American Brass Co. and perfected a fully integrated business, so as to carry its own copper all the way from the mines to the fabricated products.

In foreign affairs, the Germans carried out the Cannes agreement, making reparation payments at 10-day intervals. There was a postponement of the Genoa Conference, pending further preliminary negotiations among the powers that are likely to participate. A good deal appears to hinge upon the position of Russia, which economically can no longer be ignored, no matter how much dislike there may be for its present form of government.

The President of the United States appointed a commission comprising Messrs. Hughes, Hoover, Mellon, Smoot and Burton to make arrangements for funding the debt of the European governments to us. Fundamental economic problems will be involved in these considerations.

M. Loucheur, of the French Government, made a statement to the effect that France would be unable to pay its foreign debts, either now or at any time.

The strike of the miners on the Witwatersrand continued, all efforts to effect a settlement proving unavailing. Cable dispatches from Johannesburg, toward the end of February, reported that most of the gold mines were then working on a limited scale and more men were returning daily. If adequate police protection is provided, and this the Government has promised, it was believed the strike would shortly come to an end.

Labor troubles are to be expected anywhere and everywhere this year, for labor does not understand the controlling economic factors and even in the countries of best position the people are approaching the end of their ability to live on their fat. In most of the countries of Europe large percentages of the workers are unemployed, and of course there can be no prosperity when many workers are idle. Of all countries Germany is the most active, but even there productivity is far below pre-war level. Germany's national income in 1913 was estimated at 42 billion gold marks. For 1921, estimates range from 14 to 18 billion. Although the latter figures look rather doubtful, they assist in a visualization of the economic situation in Germany. Railway traffic in Germany, which in 1920 was only 65 per cent. of pre-war volume, had recovered to only 80 per cent. in 1921. It is becoming recognized even by socialists that people *en masse* working only 8 hr. per day, as prescribed by the League of Nations, cannot produce enough to afford them a scale of living as high as they had before the war. But obviously, many groups of workers will strike in resistance to the inexorable and non-understandable.

ANNUAL BANQUET OF THE A. I. M. E. AT THE HOTEL PENNSYLVANIA, FEB. 23, 1922.

AT THE GUEST TABLE: H. S. MULLIKEN GEORGE F. KUNZ, H. FOSTER BAIN, ARTHUR S. DWIGHT, GEORGE OTIS SMITH, EDWIN LUDLOW, WILLIAM MCCLELLAN, L. K. ARMSTRONG, ALFRED W. G. WILSON, PHILIP N. MOORE.

Digitized by Google

# The 125th Meeting of the Institute

THE 125th meeting of the Institute was held in New York, Feb. 20–23, 1922, inclusive, and was the most successful annual meeting of the Institute ever held; there was a larger registration, there were more sessions of importance, and a greater number of sessions, than in any previous year. The total registration was 1331, comprising 351 New York members, 393 visiting members and 587 guests.

At the annual business meeting of the Institute, held on Tuesday, Feb. 21, with President Ludlow presiding, there was a much larger attendance than usual. The report of the tellers was read and the following officers were declared elected:

Arthur S. Dwight, *Director and President*—District 0
J. V. W. Reynders, *Director and Vice-president*—District 0
A. R. Ledoux, *Director and Vice-president*—District 0
Charles F. Rand, *Director*—District 0
George D. Barron, *Director*—District 0
William H. Bassett, *Director*—District 1
Thomas B. Stearns, *Director*—District 8
William Kelly, *Director*—District 5

These new officers, with those who are continued in office, form the complete Board for 1922. The latter are:

VICE-PRESIDENTS

Frederick Laist—District 7
Seeley W. Mudd—District 10
E. L. DeGolyer—District 0
Albert Burch—District 10

DIRECTORS

William M. Corse—District 1
W. H. Aldridge—District 0
R. M. Catlin—District 1
G. H. Clevenger—District 1
E. P. Mathewson—District 0
R. V. Norris—District 2
W. G. Mather—District 3
George Otis Smith—District 4
W. E. Wrather—District 6
J. C. Greenway—District 9

At the Directors' meeting that followed, J. V. W. Reynders was elected First Vice-president, and C. F. Rand was made Treasurer.

Section III of Article 6 of the Constitution was amended by changing the word "six" to the word "eight," requiring eight for a quorum of the Board of Directors necessary to transact business. There were 1681 votes cast in favor of this amendment, 272 votes were cast against it, and 90 votes were marked in such a way as to be declared void by the tellers. Reports of the Secretary; the Treasurer; the Membership committee, showing a gain in membership for the year from 9323 to 10,205 as of Dec. 31, 1921; the Library committee and the Papers of Publications committee, were read and have been published. The President announced that he would incorporate his report in his speech at the banquet.

TECHNICAL SESSIONS

The technical sessions were greater in number than ever before and overflowed the ordinary space at the service of the Institute for this purpose; several sessions were held in the quarters of the other societies, which gladly donated rooms for this purpose.

The Symposium on Foreign Oil Possibilities and Details of the Oil Industry drew the largest attendance and occupied the center of interest. The oil sessions overflowed their quarters on the first day and had to be transferred to the Auditorium. Only the papers presented at the last oil session had been prepared for advance distribution, because the discussion at the earlier sessions, in many cases, dealt with the delicate situation of international policy, and for the same reason none of these sessions was reported, as were all of the other sessions. Some of the papers may be published later.

SCENE AT THE REGISTRATION DESK DURING A LULL.

The Mining Methods Committee, engaged as it is in the monumental work of collecting data from all of the

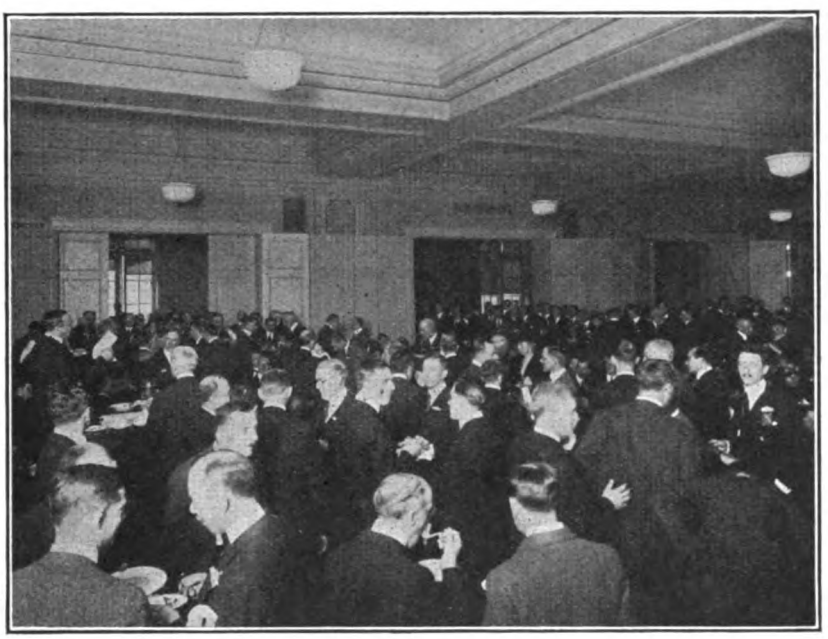
Digitized by Google

big mines of the United States to answer the questions involved in the choice of mining methods with all the necessary controlling factors, had a continuous session of well-attended meetings throughout the convention.

The Institute of Metals Division, in addition to two of the largest sessions it has held since affiliating with the Institute, conducted the lecture by Prof. Wilder D. Bancroft on Colloid Chemistry and Metallurgy, which attracted a great deal of interest. This lecture was not prepared as a paper, but may be presented in this form later.

The Iron and Steel Sessions were in part devoted to memorials of the late Prof. J. W. Richards, who was for so long its very able and efficient chairman.

The Safety Sessions were joint sessions of the Mining Section of the National Safety Council and the Industrial Relations Committee of the Institute, and another notable joint session was a meeting of the Mining and Metallurgical Society of America with the Institute, at which papers and discussions on Waste in the Mining Industry were presented. These constitute the feature of this March number.



CHAIRMAN OF THE NEW YORK SECTION HOLDING UP THE LUNCHEON TO MAKE AN ANNOUNCEMENT.

In opening this session, Allen H. Rogers, president of the Mining and Metallurgical Society, said:

It is the usual thing to speak of an event like the present as an auspicious occasion. I really feel that it is quite an auspicious occasion because it is the first time that the Institute authorities have asked the Mining and Metallurgical Society to join with them.

The Mining and Metallurgical Society, as you all know, was founded about fourteen years ago, and at the time there was a good deal of opposition to it among certain of the members of the Institute. It was felt that the Society was founded as an opposition organization; that it was founded to do the Institute harm. This has not been the case, as you all know. Those of us who are members of the Mining and Metallurgical Society (and we all, with very few exceptions are members of the Institute) know that the Society has always been very particular to avoid encroaching on the field of the Institute. The Society has felt its function to be the discussion of what we may speak of as "extra-technical" subjects, subjects having to do with policy, particularly of the mining industry as a whole.

With that thought, the aim has been to keep the membership of the Society to men of a good deal of age and experience. The younger men as they grow old naturally acquire the experience which enables them to become eligible to membership in the Society and even though the Institute has, since those early days, raised its requirements for membership, the Society still represents, in the main, men of long experience in the industry.

As illustrative of the class of subjects that the Society discusses, we have selected for the subject of discussion today "Waste in the Mining Industry." The discussion of this subject unquestionably involves a certain technical practice, but in the main, it is a broad subject, covering the industry as a whole and as such comes within the purview of the Society itself.

In approaching a subject, it is natural to take it up in its logical order and as we know, in the mining industry, the first thing to do in the case of a mineral deposit is to discover and develop it. This viewpoint of the subject, that is, as the paper was entitled, "Waste Involved in Preliminary Investigation of Mineral Deposits," was to have been treated by Mr. J. E. Spurr. He has unfortunately been called to the West and so cannot be present. We are fortunate, however, in having gained the consent of Mr. H. Foster Bain to say a few words on this subject. (See page 23.)

The next step in the industry, after having discovered the deposit and developed it, is naturally the management of it, the exploitation. We have with us today a man who stands preeminent in that branch of the field. The Mining and Metallurgical Society conferred upon him its gold medal for his proficiency in management. It will be instructive, therefore to all, and a great pleasure, to hear from Mr. Pope Yeatman regarding Factors in the Management of Mining Properties which Lead to Loss and Waste. (See page 25.)

There is another element causing waste in the mining industry and that is an economic one—one having to do with efficiency, perhaps more particularly of labor; and we have with us Mr. W. R. Ingalls, who is very competent to treat of that branch of the subject. He has been two or three times the president of the Mining and Metallurgical Society. He is a mining engineer and a metallurgist who specializes more particularly in zinc metallurgy, and recently he has gotten a national prominence as an economist. Mr. Ingalls will present his paper on Elimination of Waste and the Improvement of Efficiency. What are the Economic Fundamentals? (See page 33.)

The relation of waste to the anthracite and bituminous coal industries will be discussed by Mr. Edwin Ludlow, the retiring president of the Institute, who has been a large operator in both hard and soft coal; and, lastly, Mr. J. Parke Channing, chairman of the committee on waste in industry of the Federated American Engineering Societies, will review the subject and the work of the committee. (See pages 39 and 41.)

Another innovation at this meeting was a Local Section Convention, at which the chairmen and secretaries of the various local sections, or in their absence their representatives, gathered to discuss local section problems as related to the Institute and its problems as related to the local sections. The new

Digitized by Google

president of the Institute, Col. Arthur S. Dwight, presided. This convention proved to be such an interesting feature that the one session provided for its initial meeting was entirely inadequate, and it is hoped and expected that it will become a permanent feature of the Institute meetings.

Heretofore, the Iron and Steel Committee and the Executive Committee of the Institute of Metals Division have held the only Committee dinners but this year the Petroleum and Gas Committee, the Industrial Relations Committee, the Mining Methods Committee, and the Milling Methods Committee also met at dinner or luncheon. These gatherings proved so interesting and inspiring that it is expected that they will be continued and that the number of committees to hold such functions will be increased.

The Industrial Relations Committee and the Non-Metallic Committee had interesting technical sessions. The Institute Committee on Ground Movement and Subsidence, and the Committee on Breakage and Heat Treatment of Drill Steel, appointed last year as an advisory committee to the Bureau of Mines, held meetings on Monday morning. The last-named committee has been made permanent and has been promised support by the Bureau of Mines for a special investigation. Technical sessions were as follows:

**Symposium on Foreign Oil Possibilities and Details of the Oil Industry**

Chairman, Ralph Arnold

TUESDAY MORNING, FEB. 21

Introductory Remarks. Ralph Arnold.
Addresses on: Oil Reserves of United States. David White.
Canada. Ralph Arnold and Walter A. English.
Mexico. V. R. Garfias.
Trinidad. Ralph Arnold.
West Indies, except Trinidad. A. H. Redfield.
Central America. A. H. Redfield.
Colombia. Chester W. Washburne and K. D. White.
Venezuela and the Guianas. Ralph Arnold and B. Bryan.

TUESDAY AFTERNOON

Addresses on: Oil Reserves of Peru and Ecuador. V. F. Marsters.
Bolivia. C. W. Washburne.
Argentine and Chile. E. W. Shaw.
Brazil. J. C. Branner.
Japan. J. Morgan Clements.
China and Siberia. Eliot Blackwelder.
Philippines. W. E. Pratt.
Galicia. R. N. Ferguson.
Europe, Africa, Asia, Australia, New Zealand, and East Indies. A. Beeby Thompson and Robert Anderson.

WEDNESDAY MORNING, FEB. 22

Addresses on: Suggestions for Stabilizing the Oil Industry. Henry L. Doherty.
Oil Laws of Latin-American Countries. Edward Schuster and Frank Feuille.
What the State Department Can do to Aid in Foreign Oil Development. Lester H. Woolsey.

WEDNESDAY AFTERNOON

Future Demands on Oil Industry of United States. By J. E. Pogue.
Time to Pay out as a Basis for Valuation of Oil Properties. By W. Irwin Moyer.
Production Problems of Grass Creek Oil Fields. By E. L. Estabrook.
Possible Origin of Oil. By Colin C. Rae.
Subsurface Conditions on Portion of Arches Fork Anticline. By K. Cottingham.

**Mining Sessions**

MONDAY AFTERNOON, FEB. 20

Chairman, B. B. Gottsberger

Sampling and Estimating Ore Deposits. Introductory Remarks by B. B. Gottsberger.
Diamond-drill Sampling Methods. By R. D. Longyear.
Sampling and Estimating Disseminated Copper Deposits. By I. B. Joralemon.
Sampling and Estimating Iron-ore Deposits:
Lake Superior Iron District. By J. F. Wolff, E. L. Derby, and W. A. Cole.
Gogebic Range. By J. F. Wolff.
Menominee Range. By J. F. Wolff.
Marquette Range. By R. W. Bowers.
Sampling and Estimating Zinc and Lead Orebodies of Mississippi Valley. By W. F. Boericke.
Organization of Mine Sampling at Anaconda. By W. B. Daly and F. A. Linforth.

TUESDAY MORNING, FEB. 21

Chairman, William Kelly

Storage-battery Locomotive as Applied to Mine Haulage. By Charles E. Stuart.
Electric Haulage Systems in Butte Mines. By C. D. Woodward.
Handling Ore in Mines of Butte District. By H. R. Tunnell.
Power Distributing System for Deep Metal Mines. By C. D. Woodward.
Effect of Rate of Production on Profits. By W. O. Hotchkiss.

TUESDAY AFTERNOON

Chairman, E. E. Hunner

Introductory Remarks on Work of Mining Methods Committee. By John E. Hodge.
Mining Engineers. By Arthur Thacher.
Recovery of Tonnages and Values under Various Mining Methods. By Henry Krumb.
Nomenclature of Mining Methods. By F. W. Sperr.
General Outlines for Obtaining Data. By E. E. Hunner.
Discussion by Messrs. Charlton, Gillies, Hotchkiss, Jackson, Kelly, Kemp, Linton, Raymond, Sebenius, Stoek, Westervelt, Yeatman.
Spies Open-stope System of Mining. By S. R. Elliott.
Stope Cost Records and Mine Contracts of A. C. M. Co. By C. I. Berrien.
Steam-shovel Operations at Bisbee, Ariz. By H. M. Ziesemer and George Mieyr.
Mining Methods at the Ashio Copper Mine. By M. Otagawa.

WEDNESDAY MORNING, FEB. 22

Chairman, Howard N. Eavenson

Systems of Mining in Pocahontas Coal Field, and Recoveries from Them. By T. H. Clagett.
Discussion by Messrs. Gay, Haas, Peltier, Ramsay, Cox, and Newbaker.
Can Anthracite Mines be Operated Profitably on More than One Shift? By D. C. Ashmead.
Some Considerations Affecting the Extraction of Bituminous Coal in American Mines. By H. H. Stoek.

Studies on the Constitution of Binary Zinc-base Alloys. By Willis McG. Peirce.

**Iron and Steel Sessions**

WEDNESDAY MORNING, FEB. 22

Chairman, Bradley Stoughton

This session was in memory of Prof. J. W. Richards.

Application in Rolling of Effects of Carbon, Phosphorus and Manganese on Mechanical Properties of Steel. By W. R. Webster.
Acid Open-hearth Process for Manufacture of Gun Steels and Fine Steels. By W. P. Barba and Henry M. Howe.
Effect of Sulfur and Oxides in Ordnance Steels. By W. J. Priestley.
Electrolytic Deposition of Iron for Building up Worn or Undersized Parts. By D. R. Kellogg.

WEDNESDAY AFTERNOON

Chairman, C. P. Perin

Effect of Time in Reheating Quenched Medium-carbon Steel Below the Critical Range. By C. R. Hayward, D. M. MacNeil, and R. L. Presbrey.
Effect of Quality of Steel on Case-carburizing Results. By H. W. McQuaid and E. W. Ehn.
Malleableizing of White Cast Iron. By Arthur Phillips and E. S. Davenport.

**Joint Meeting with Mining and Metallurgical Society**

WEDNESDAY AFTERNOON, FEB. 22

Chairman, Allen H. Rogers, President, M. & M. S. A.

Waste Involved in Preliminary Investigation of Mineral Deposits. By H. Foster Bain.
Factors in Management of Mining Properties Which Lead to Loss and Waste. By Pope Yeatman.
The Elimination of Waste and the Improvement of Efficiency. What are the Economic Fundamentals? By W. R. Ingalls.
Waste in the Coal-mining Industry. By Edwin Ludlow.
The Engineer's Relation to Elimination of Waste in Mining. By J. Parke Channing.

**Local Section Convention**

WEDNESDAY AFTERNOON, FEB. 22

Chairman, Arthur S. Dwight

Informal Discussion of Matters of Interest to the Sections, and Address by L. W. Wallace on the Federated American Engineering Societies.

## THE SMOKER

The annual smoker was held on the fifth floor, Monday night, and packed its capacity, partly due to the large attendance at the technical meetings and more probably due to the seductive notice of the smoker published by the Entertainment Committee, as follows:

* Will not be published by the Institute. Paper of the U. S. Bureau of Mines.

† Joint Session of Mining Section of National Safety Council and Industrial Relations Committee of the Institute.

‡ Published elsewhere, and therefore will not be published by the Institute.

**J'AIME**

*will present*

**FOLIES MINIERES**

A Revue with Pangs

Fresh from Roaring Camp Theater, Death Valley
With the original cast, including

**Prince Albert, Ricoro, Fatima and the Camel Family**

A wireless telephone furnished musical numbers from a broad-casting station west of the Hudson River. These numbers were interspersed with fake wireless messages, which were telephoned from an outside room, perpetrating various jokes on Institute members and the more or less hectic happenings of the past year, particularly with reference to publication.

The Entertainment Committee offered a prize for the best limericks, and many of these, which were projected on the screen, elicited much fun and applause. After the last one had been shown, Professor Kemp, with his usual inimitable humor, presented the prize, together with a consolation prize, and in addition, a silver-topped cigar jar to F. F. Sharpless, the Secretary

Lawrence Addicks started the limerick idea and then started for Europe.—Safety First? A few of the many clever rhymes submitted are printed below:

Now, who is this Arthur S. Dwight,
Our president after tonight?
He can sinter fine ore,
Win honors in war
And Institute Members delight.

A man who's sincere as polite
Whose doings all square with what's right
A man of broad vision,
Of mental precision—
Who is it? Of course Arthur Dwight.

The Engineers working for Dwight
Were technically put into flight
But they broke all the rules
For they picked up their tools
And put up a helluva fight.

A mucker whose surname was Hall
Fell into the sump, boots and all
'Twould have been a sad thing
If he'd died in the spring
But he didn't; he died in the fall!

We're asked for suggestions on Copper
Here's one that's both fitting and proper
"Just get the right dope
Add a measure of hope
And apply with a medicine-dropper."

There was an old buck from the west,
Who said, as he pulled on his vest,
My clothes are spun copper
Which style is most proper
To strengthen a metal depressed.

There once was a young Russian Colonel,
Who invented a banner infolonel;
It waved with a roar
And was Red (what was more—)
Sheet Copper, the metal Etolonel.

BUFFET LUNCHEON ON THE FIFTH FLOOR OF INSTITUTE HEADQUARTERS.

The Institute's Lieut. Col.
Is running a new mining jol.
But Rickard and Spurr
Have kicked up a stir
As if the whole thing were infol.

There was a Director, named Rand,
All gentleness mingled with sand.
He tamed the wild Civils,
Who'd acted like divils,
And now they eat out of his hand.

Charlie Goodale is with us from Butte,
On his annual mid-winter toot,
You may Charlie behold
With a medal of gold
Which just seems its owner to suit.

During the first half of the entertainment, one end of the room was concealed by a curtain; when this was drawn, it revealed a regular, honest-to-goodness, old-fashioned, mining-camp bar-room scene, with a 24-ft. bar, all of the plate-glass mirrors, bronze ladies holding colored electric lights, the usual bottles and signs and

two beer kegs, one on each end of the bar. Lined up in front of the bar were half a dozen miners and cowboys in slouch hats, red shirts, chaparejos, six-shooters and all of the fixings to make the picture realistic. This group was composed partly of professional entertainers and partly of Institute members. There was a piano at the end of the bar and the professional entertainers using this had a typical western mining-camp entertainment especially prepared for the occasion, which vividly brought back the by-gone days and aroused much enthusiasm and applause from the audience. In the midst of the hilarity, a desperado with his face veiled by a black and white checkered handkerchief rushed in and held up the entertainers in what used to be true Wild Western style but should now be called true New York style.

The bar and the surrounding walls were covered with most interesting and realistic signs. For example, on one end a sign announced "First Chance, Wash the Dust Out of your Mouth," "Last Chance, 25 Miles to Tonopah." At the other end, "The Stage Stops for Five Drinks." A most appropriate sign was one occupying the place of honor on top of a long necker in the middle of the bar (which probably came from the National Safety Council), which read

DANGER

KEEP OFF THIS TIPPLE

SAFETY FIRST

After the fixed entertainment, the invitation came over the wireless telephone to liquor up and from then on to the end of the evening the bar was a busy place. For those who did not like near-beer (nor the contents of the kegs) there was cider and coffee for some, and free lunch for all. It was the Institute's most pretentious and best attended smoker and many congratulations were offered to A. C. Ludlum and his committee.

### The Banquet and Other Social Events

On Tuesday evening, the large room on the fifth floor was filled with members and guests to see two moving pictures, entitled "Mexico and Its Oil" and "Through India with the Duke of Connaught, including a visit to the Tata Iron and Steel Works," fine and interesting films. Following these the room was cleared of seats and an informal dance was held.

On Wednesday evening the Institute's annual banquet and ball were held in the grand ballroom of the Pennsylvania Hotel; 645 covers were laid, making it within seven of the largest banquet the Institute has ever held at its annual meeting. George Otis Smith, of the U. S. Geological Survey, was toastmaster and the only two speakers were our retiring and newly elected presidents, Edwin Ludlow and Col. Arthur S. Dwight.

Past President Edwin Ludlow, in his speech, took up in considerable detail the work of the Institute during the year of his administration, giving figures of the financial condition, the increase in membership, and the improved condition of the magazine Mining and Metallurgy. He spoke at length on the local sections, their increasing number and their growing usefulness to the parent body. The year of his administration was a memorable one, being the 50th anniversary of the Institute, which was celebrated by a notable meeting at Wilkes-Barre in September, 1921. He reviewed the amenities between the English and French societies and the national engineering societies of this country resulting from the visit of the John Fritz Medal Delegation to confer medals on Sir Robert Hadfield and Eugène Schneider, and also reviewed the work of the Federated American Engineering Societies, with which he is connected as a member of American Engineering Council.

Colonel Dwight said: "It has become the time-honored custom at these annual dinners of ours to put upon the outgoing president the duty of talking about Institute affairs, and to leave the incoming one considerable freedom in choosing his own subject and perhaps to inflict upon his friends some ideas that he might not be allowed to perpetrate at any other time." His address* was entitled "Prospecting and Research," and was a tribute to the old prospector who has now "disappeared into the limbo of the past, with the red man and the buffalo; vanished before the very tide of civilization and progress of which he was the forerunner, and which, indeed, he himself evoked."

Colonel Dwight sees scientific research considered in its broadest sense as the natural successor of the prospector, who, though quite necessary in the beginning of the discoveries of our mineral deposits, has been eliminated by the very conditions that made for perfection in the industry. He believes that "It is not only along mechanical lines that we need stimulation. We must look to the geologist to shape his studies more and more toward the practical requirements of the miner, and to change his role from that of historian after the fact to that of prophet and leader. He must find a way to tell us the nature of the hidden orebody and its relative richness by reading the handwriting of Mother Nature that he finds in the weathered rocks of the outcrop, or the neighboring rocks of the deeper workings, so that the miner may confidently follow his indications. He must discover the Rosetti Stone that will furnish the key to interpret these hieroglyphics of the Earth Gods."

"In the field of metallurgy the possibilities are still more evident. The research work that is being done is concerning itself principally with the products rather than with what may be called the grand problems of metallurgy, for there is a crying demand from the trade for improving the quality of the metallic prod-

ucts, eliminating impurities, forming new alloys with special properties; but established industry is instinctively conservative when it comes to anything that might threaten the value of existing plant investment. The inclination is to let well enough alone, and let the other fellow do the experimenting if he wants to. Therefore, the thought of fundamental changes in process or apparatus is not always a welcome one, and comparatively little encouragement is offered for this kind of research on the larger working scale necessary for the convincing demonstration of any new process. This is natural enough, but does not make for progress." "All these questions depend, in the last analysis, on the human factor, for a skillful metallurgist will produce better results with a tumble-down, out-of-date plant, than his less resourceful neighbor may with all the modern improvements."

These annual banquets go off so smoothly under the skillful hand of Captain D. M. Liddell, chairman of the committee, that few people realize the tremendous amount of work involved, necessitating almost invariably one sleepless night before the event. The mathematical seating arrangements for "first come, first served" works out very well, but entire tables are often purchased by members arranging their own guests. One table seating list of this kind was changed five times. Some diners thoughtlessly took seats near friends whom they had not seen for a long time, regardless of the fact that these seats had been assigned to others. The work of this committee is increased by the fact that the individual wishes and prejudices of all the members are catered to so far as is possible. Captain Liddell suggests that it would be a grand experience to make out the seating arrangement according to his own desires, get it into print just before the dinner and leave immediately for parts unknown.

Lunches were served every noon on the fifth floor, as in years past, but the law of averages failed to work in 1922. The first day lunches were provided for the largest number that had ever attended such functions, plus a factor of safety, yet the caterer was eaten out of house and home before everyone was supplied. Arrangements were made to supply the correspondingly large number on Tuesday, but there again the attendance at the meetings exceeded expectation. The hungry members were lunched at the club. A third effort was made on Wednesday and not only was every one supplied but a most delightful lunch was provided. The ladies attended these lunches, excepting on Tuesday. This is a feature that is not a part of the conventions of the other national engineering societies.

Senator William A. Clark generously opened his art galleries to the members and guests of the Institute. More than 500 tickets were issued at the Registration Desk to those who desired to enjoy this rare treat, for which we have been indebted to Senator Clark so many times. As usual, a delightful tea at Senator Clark's home followed the inspection of his art collection.

"I'M OUT OF IT ANYWAY"
"IF THEY ARE GOING TO ROAST ME, I HOPE THEY WILL AT LEAST USE A GOOD MACHINE FOR IT."
DWIGHT
LUDLOW
ANYWAY THERE MIGHT HAVE BEEN MORE SPEAKERS
IT HAS BEEN A HARD YEAR FOR ENGINEERS"

CARTOON ON COVER OF MENU AT ANNUAL BANQUET.

## ENTERTAINMENT OF LADIES

The Womans' Auxiliary had a longer and more attractive, and probably more strenuous, program than usual. A full report of the events will appear in the April MINING AND METALLURGY. As outlined on the program, they included a reception by Mr. and Mrs. Edwin Ludlow at the Hotel Ambassador, a luncheon and card party given by Mrs. George D. Barron at her home in Rye, visits to the Roosevelt Memorial and other places of interest, and a theater party.

## EXCURSIONS ON THURSDAY

The fourth day of the convention was devoted to excursions, which this year were made to various industrial plants in New Jersey. The excursionists assembled at the Ferry House of the Central Railroad of New Jersey at the foot of West 23rd St. at 8.55 a.m. This place of meeting was chosen both for convenience

Digitized by Google

and to give the out-of-town visitors who arrived by tunnel the opportunity of seeing the New York waterfront on the trip down the river to the Central Railroad Terminal in Jersey City. The ferry boat got lost in the fog, and not only was the New York skyline not visible, but the party was an hour late in reaching its destination. However, the weather changed and on the return trip in the evening the tall buildings with their myriad lighted windows presented a beautiful picture.

The special train from Jersey City took the oil group to the Bayway plant of the Standard Oil Co. (N. J.); the steel group to the plant of the Crucible Steel Co. of America, Harrison, N. J., and the copper group to the Chrome plant of the U. S. Metals Refining Co. About two hours was allowed for seeing these plants. The special train collected the different groups and took them to Perth Amboy, N. J., where they were entertained at luncheon by the Industrial Association of that city.

The gymnasium at the Y. M. C. A. had been converted into a large dining room, seating 400 people, and a delicious luncheon was served by ladies of Perth Amboy. The committee representing the Industrial Association included A. Clayton Clark, C. C. Baldwin, Nathaniel Pierce, G. H. Hawley, J. N. Pyster, Joseph Slutzker, C. W. Hill, John Pfeiffer, R. W. Atkinson, H. W. Fisher and Albert Waters.

The ladies entertainment committee consisted of Mrs. C. C. Baldwin, Mrs. Ferdinand Andrews, Mrs. Kenneth McComas, Mrs. J. V. Shull, Mrs. William DeHaven, Mrs. A. Clayton Clark, Mrs. Peter C. Olsen and Mrs. Nathaniel W. Pierce.

In the afternoon, many of the ladies were entertained at the Raritan Yacht Club, and a few accompanied the members and men guests on visits to the copper-fabricating plant of the Standard Underground Cable Co.; the copper-refining plant of the Raritan Copper Works, where oil is largely used as fuel; the roofing plant of the Barber Asphalt Paving Co. at Maurer, N. J., or the refractory plant of Henry Maurer & Son.

The groups reassembled on the special train, and reached New York at 6 p. m.

It is difficult to adequately describe these trips or to do justice to the courtesy and painstaking care of the plants entertaining the visitors. Each plant had been carefully organized; the party was divided into small groups, each group in care of a guide who conducted his party over a stipulated route and freely answered the questions asked. Souvenir booklets, printed descriptive matter, and souvenirs were distributed. At both of the copper refineries large amounts of gold and silver bullion and other precious metals, as well as samples of copper ore in various stages of preparation, and the refined product, were exhibited. Each visitor to the U. S. Metals Refining Co. at Chrome came away with a beautiful little copper ingot and from the Raritan Refining Works of the Anaconda company with a little copper wire bar.

## Appreciation Recorded

The Board of Directors, at its meeting on Tuesday, passed the following resolution:

**Resolved that the thanks of the Institute and of the Board of Directors be most heartily extended to the Chairman and Members of the Committees who so admirably carried out the program and arrangements of the 125th Meeting of the Institute.**

**Our thanks are also extended to the women who assisted in the entertainment of our guests and to members who so generously contributed their financial support.**

The committees responsible for this successful meeting were:

*General Executive Committee.*—William Young Westervelt, *chairman;* Robert Linton, *vice-chairman;* E. L. Gruver, *secretary;* C. C. Burger, John A. Church, Jr., William C. Coffin, Ralph W. Deacon, E. L. DeGolyer, J. V. N. Dorr, Karl Eilers, Fred Hellmann, Louis D. Huntoon, C. V. Jenkins, Wilber Judson, Donald M. Liddell, Richard L. Lloyd, Albert C. Ludlum, Harris K. Masters, John A. Mathews, A. J. McNab, Carl A. Meissner, P. A. Mosman, Herman A. Prosser, R. M. Raymond, Sidney Rolle, Forest Rutherford, Bradley Stoughton, Arthur L. Walker, Daniel A. Welch, Mrs. Arthur S. Dwight.

The sub-committees were made up as follows:

*Finance Committee.*—Karl Eilers, *chairman;* Walter H. Aldridge; George D. Barron; W. A. Clark; W. E. Corey; Walter Douglas; Arthur S. Dwight; H. W. Hardinge; Albert R. Ledoux; L. D. Ricketts; John D. Ryan; Benjamin B. Thayer.

*Banquet Committee.*—Donald M. Liddell, *chairman;* C. C. Burger, *vice-chairman;* G. P. Bartholomew; Colin Garfield Fink; George F. Kunz; Ralph S. Rainsford; Richard H. Vail; Mrs. Colin G. Fink.

*Entertainment Committee.*—Albert C. Ludlum, *chairman;* Louis D. Huntoon, *vice-chairman;* Lawrence Addicks; C. A. Burdick; Lucius W. Mayer; Theodore Pilger; Frederick Taber Rubidge; Ernest E. Thum.

*Excursion Committee.*—Ralph W. Deacon, *chairman;* Sidney Rolle, *1st vice-chairman;* A. W. Carroll, *2nd vice-chairman;* D. E. A. Charlton; Thomas E. Fisher; Philip W. Henry; Frank H. Ramsey; Stanislaus Showronski; Frederic R. Weekes.

*Hotel Committee.*—Wilber Judson, *chairman;* A. J. McNab, *vice-chairman;* H. N. Spicer; Frederic Richmond Kennedy.

*Luncheon Committee.*—P. A. Mosman, *chairman;* Forest Rutherford, *vice-chairman;* Charles A. Bohn; Guy C. Riddell; Andrew W. Newberry.

*Reception Committee.*—R. M. Raymond, *chairman.*

*Ladies' Committee.*—Mrs. Arthur S. Dwight, *chairman;* Mrs. W. H. Aldridge; Mrs. P. E. Barbour; Mrs. G. D. Barron; Mrs. C. A. Bohn; Mrs. C. C. Burger; Mrs. A. W. Carroll; Mrs. D. E. A. Charlton; Mrs. J. A. Church; Mrs. W. C. Coffin; Mrs. Karl Eilers; Mrs. R. W. Deacon; Mrs. E. L. DeGolyer; Mrs. Walter Douglas; Mrs. C. G. Fink; Mrs. E. L. Gruver; Mrs. H. K. Hardon; Mrs. H. W. Hardinge; Mrs. Fred Hellman; Mrs. Levi Holbrook; Mrs. P. W. Henry; Mrs. L. D. Huntoon; Mrs. S. J. Jennings; Mrs. C. V. Jenkins; Mrs. F. R. Kennedy; Mrs. J. F. Kemp; Mrs. A. R. Ledoux; Mrs. D. M. Liddell; Mrs. Robert Linton; Mrs. R. L. Lloyd; Mrs. Edwin Ludlow; Mrs. A. T. McNab; Mrs. E. P. Mathewson; Mrs. H. A. Prosser; Mrs. R. M. Raymond; Mrs. J. V. W. Reynders; Mrs. G. C. Riddell; Mrs. Sidney Rolle; Mrs. F. T. Rubidge; Mrs. H. W. Spicer; Mrs. Bradley Stoughton; Mrs. F. F. Sharpless; Mrs. F. R. Weekes; Mrs. W. Y. Westervelt. Miss Marguerite Eilers, *junior committee chairman.*

Mimeographed lists of those in attendance may be secured at Institute headquarters.

# The Presidents of the Four National Engineering Societies

## Arthur Smith Dwight

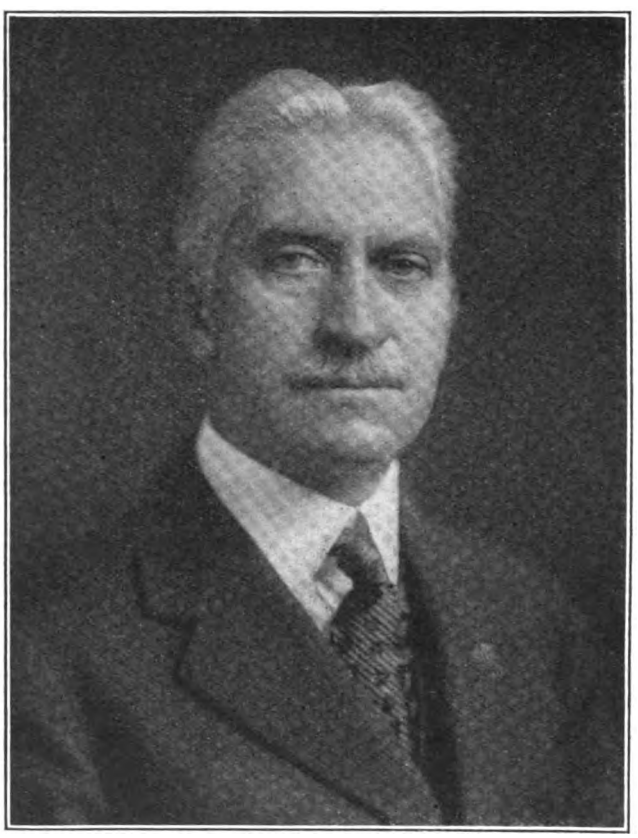
ARTHUR SMITH DWIGHT, president of the American Institute of Mining and Metallurgical Engineers, was born in Taunton, Mass., on March 18, 1864. He is descended on both sides from early settlers, one of whom was Richard Warren, of the "Mayflower." His forebears included Col. Benjamin Church, Timothy Dwight, and the Rev. Jonathan Edwards, third president of Princeton College.

Mr. Dwight was graduated in 1882 from the Polytechnic Institute of Brooklyn, N. Y., and three years later from the Columbia School of Mines, with the degree of Engineer of Mines. In 1914, he received the honorary degree of Master of Science from Columbia.

On leaving Columbia in 1885, he went to Pueblo, Col., and for thirteen years was associated with the Colorado Smelting Co. Beginning as assayer he rose to be general superintendent. When he gave up the latter position he became connected with several large companies in the mining and smelting of lead, copper and the precious metals in the Rocky Mountain region. This work occupied him from 1897 to 1906, and six years of that time were spent in Mexico. He was general manager of the Greene Consolidated Copper Company at Cananea, Mexico, in 1906, when trouble first developed against the régime of Diaz. A general uprising was planned to seize the mines, and with money and supplies so obtained, carry the revolt through the interior. Mr. Dwight turned his industrial organization into a military unit almost over night, stemmed the tide of revolution, and had the situation well in hand before the arrival of troops.

In the fall of 1906 he returned to New York and began practice as a consulting mining and metallurgical engineer. He next developed important metallurgical patents for the roasting and agglomeration of fine ores, known as the Dwight and Lloyd sintering process, now extensively used all over the world.

When the World War began Mr. Dwight became convinced that the United States must eventually enter the fight and he took an active part in preparedness work, particularly in his own profession. He was a member of an engineering committee that coöperated with the War Department in obtaining the creation of the Engineer Officers Reserve Corps, which resulted in a large number of engineers being available when we declared hostilities. Mr. Dwight was one of the first civilians to be commissioned in the Reserve and to enter active service. As Major in the First Reserve Engineer Regiment, he had an important part in recruiting and training that body, which sailed for France on July 14, 1917, as the Eleventh Engineers. This was the first unit of the A. E. F. in action. The behavior of these engineers at Cambrai on Nov. 30, 1917, when they fought the Germans with pick and shovel, thrilled all America.



ARTHUR S. DWIGHT

Major Dwight served in France for more than twenty-two months, nine months of which was spent on the British front. At the request of the French Government he was assigned as special metallurgical advisor to French companies engaged in war work. He was next appointed Engineer Salvage Officer, A. E. F. to organize a reclamation service for the great quantities of war material being wasted on the battlefields. After the armistice he returned home and was discharged in May, 1919. He now bears the rank of Lieutenant-Colonel of Engineers, U. S. Reserve. He received

Digitized by Google

the D. S. O. from the British and a citation by General Pershing.

Besides being a life member of the American Institute of Mining and Metallurgical Engineers, he is vice-president of the New York Post, Society of Military Engineers; member of the Executive Board, American Engineering Council; member of the Mining and Metallurgical Society of America; honorary member, Institution of Mining and Metallurgy, London; Military Order of the World War; Engineers, University, and Columbia University Clubs, New York and the Engineers' Country Club.

In 1895, Mr. Dwight was married to Miss Jane Earl Reed, daughter of the late Samuel B. Reed, of Joliet, Ill., who built the Union Pacific Railroad. She accompanied him throughout his pioneering days and after his departure for France succeeded in following, undertaking relief work with the French Red Cross. In January, 1918, she became Regional Directress of the women workers with the Y. M. C. A. at the American front. She was decorated by the French Government with the Croix de Guerre for bravery, and also received other citations.

Mr. Dwight has written extensively on engineering subjects and has been an occasional lecturer at Columbia, of which he is a trustee. He is president of the Dwight & Lloyd Sintering Co. and the Dwight & Lloyd Metallurgical Co.

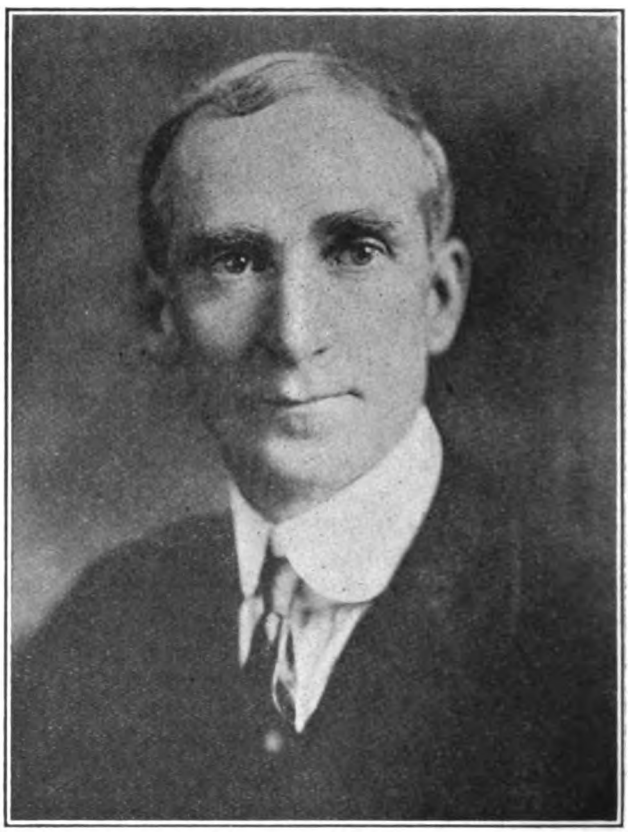
## Dexter S. Kimball

DEXTER S. KIMBALL is the president of the American Society of Mechanical Engineers, elected at the annual meeting in December. Born in New River, New Brunswick, Canada, in 1865, he was educated in California, at Leland Stanford Jr. University. He received the degree of A. B. in 1896, and of M. E. in 1913.

He served his apprenticeship with Pope & Talbot, Port Gamble, Wash., and in the shops and the engineering department of the Union Iron Works, San Francisco. In 1898 he became designing engineer for the Anaconda Mining Co. For three years he served as assistant professor of machine design at Sibley College, Cornell University, then became works manager of the Stanley Electric Manufacturing Co., Pittsfield, Mass. In 1904 he returned to Cornell University as professor of machine design and construction, and since 1915 has occupied the chair of industrial engineering. He became dean of the College of Engineering in 1920.

Dean Kimball is also a member of the Society for the Promotion of Engineering Education, the Society of Industrial Engineers, and of the honorary societies Sigma Xi and Tau Beta Pi, and since 1911, has been a member of the Council on Industrial Engineering of the New York State Department of Education. He is vice-president of The Federated American Engineering Societies.

He is co-author with John H. Barr of "Elements of Machine Design" and is author of "Industrial Education," "Principles of Industrial Organization," "Elements of Cost Finding," and "Plant Management," as well as of many contributions to the technical press.



DEXTER S. KIMBALL

## John Ripley Freeman

JOHN RIPLEY FREEMAN, of Providence, R. I., was elected president of the American Society of Civil Engineers on Jan. 18, 1922. Mr. Freeman received the B. S. degree from Massachusetts Institute of Technology in 1876; an honorary Sc. D. from Brown University in 1904, and from Tufts College in 1905.

For 10 years, 1876-86, Mr. Freeman was principal assistant engineer for the Water Power Co. at Lawrence, Mass., and for eight of those years was also assistant to Hiram F. Mills, consulting engineer. He was Water Commissioner in Winchester, Mass., for four years; chief engineer of the investigations for the Charles River Dam, in 1903; he planned the water-power developments on Feather River, Cal., at Long Sault on the St. Lawrence in 1904 and at the Lachine Rapids in 1914.

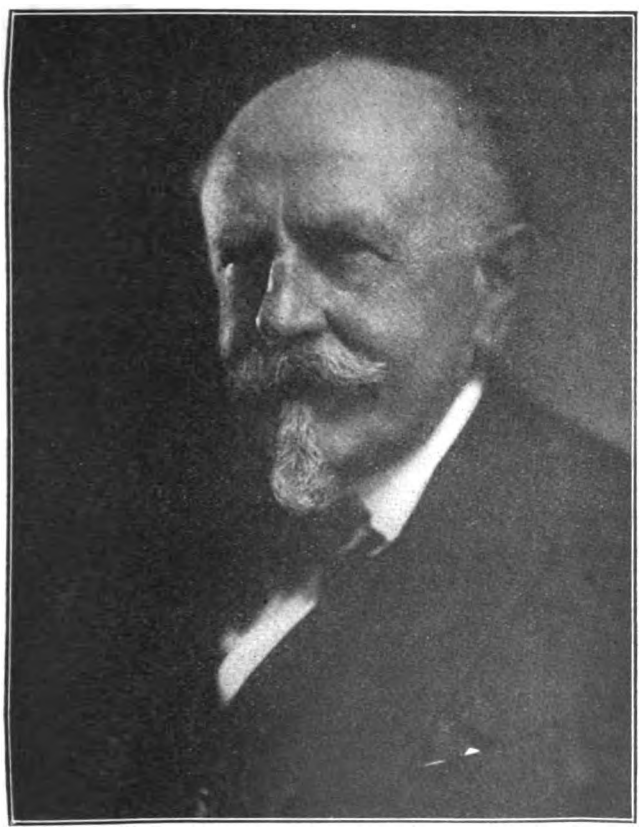
He has been consulting engineer on many large water-supply and water-development projects, and has made extensive studies on safeguarding life in theaters, and on sanitary and drainage problems. He was consulting engineer on the Isthmian Canal locks and

Digitized by Google

dams, in 1907 and 1909; since 1910, he has been consulting engineer for the San Francisco water supply, and he planned the Hetch Hetchy supply now being built.

At the present time, he is also consulting engineer to the New York Board of Water Supply and to the Grand Canal Improvement Board of the Chinese Government, as well as to various large manufacturing corporations for their water and mill construction.

Mr. Freeman has twice received the Normal medal from the A. S. C. E. for the best engineering paper contributed to its Transactions during the year. He was president of the Boston Society of Civil Engineers in 1893; vice-president of the American Society of Civil Engineers in 1902–03, and president of the American Society of Mechanical Engineers in 1904.

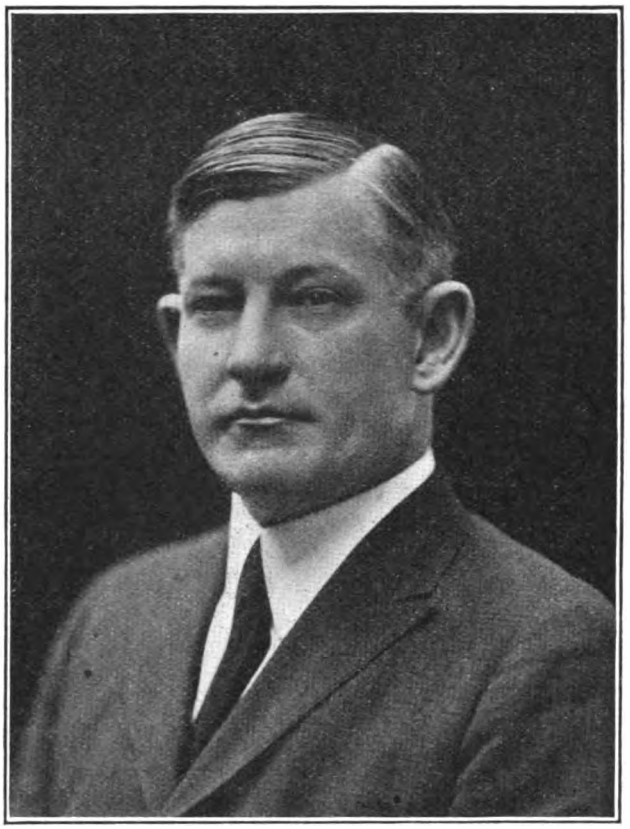


JOHN R. FREEMAN

## William McClellan

WILLIAM McCLELLAN was elected president of the American Institute of Electrical Engineers for the year beginning Aug. 1, 1921. He is a Philadelphian, by birth and education. He was graduated from the University of Pennsylvania in 1900 with the degree of B. S., later took the Ph. D. degree, and in 1913 received the degree of E. E.

Mr. McClellan's early experience was as engineer in charge of construction with the Philadelphia Rapid Transit Co. For several years he was managing engineer with Westinghouse, Church, Kerr & Co., participating in the Pennsylvania Terminal engineering and construction and electrifying the Rochester Division



WILLIAM McCLELLAN

of the Erie Railroad; for several years he was electrical engineer and chief of Division of Light, Heat and Power of the Second District Public Service Commission of New York. He has been associated with the Cleveland Electric Illuminating Co. for about eight years and was for two years one of its vice-presidents. He is a member of the firm of McClellan & Junkersfeld, recently incorporated.

During the war he was director of the Intercollegiate Intelligence Bureau, an organization of more than two hundred of the principal colleges of the United States. For a time he was dean of Wharton School of Finance and Commerce of the University of Pennsylvania.

**The First-aid Training** of the Bureau of Mines is being given extensively in the southern California oil-producing districts. At El Segundo, Calif., 70 employees of an oil-refining company recently completed the course. At Platteville, Wis., first-aid and mine-rescue instruction has been given to the students of the Wisconsin State Mining School. At the request of the Los Angeles Fire Department, the city firemen of that municipality have been given the instruction. The senior and junior students of the Mining College of the University of Wisconsin at Madison, Wis., have also recently taken the course.

# Waste Involved in Preliminary Investigation of Mineral Deposits*

By H. FOSTER BAIN

Director of the Bureau of Mines, Washington, D. C.

THIS subject is one that has attracted my attention for a good many years. All of us have had occasion to think of the waste that comes from the poor organization of our methods of finding mines and of looking after prospects. Probably all of us, in examination work, have made a long and difficult journey to see some prospect, in a far country, or often in the mountains, have found the prospect one that never could be developed, and have learned for the first time that it had been previously examined by from two to six of our professional associates, who, each in turn, condemned the property as worthless.

I know properties, as all of you do, that have been repeatedly examined by first-class engineers. Perhaps it would not be safe or wise to have an invariable rule that each prospect should be entitled to only one examination by one engineer; and yet, it seems to me that somewhere there is a middle ground to take; it is hardly necessary that each little prospect should be examined so many times that the walls get greasy from the climbing of mining engineers, or the stopes get filled up with cigarette stumps. This mining engineering profession ought to have brains enough to find some way of making this unnecessary, and of making the benefit of an examination, in some cases at least, and in a much larger number of cases than at present, available to the industry as a whole.

If we would save the amount of money that is spent unnecessarily on reëxamination of properties, and let that money flow into the actual development of properties, I believe that, in the long run, we would be better off. Just how to do that is another problem.

In 1916, while in London, Edgar Rickard and I attempted to do something of that kind. We started to organize a plan whereby mining engineers might, with the consent of their class, turn over to a central organization their reports on properties they had examined, whereby men who had occasion to look up these same properties might, on payment of a fee (which should go back to the original client, if you desire, or might be devoted to some other purpose for the benefit of the industry), have access to these earlier reports. We found, in the short time we considered this matter, that a good many British engineers, and a good many of the companies, were willing to consider this. In other words, they were willing to pool their information, as a matter of practical experience. We all know the enormous value of pooling information. I think it is a problem that may well be considered from the point of view of the industry as a whole, which the Society might attempt to work out on a businesslike basis.

Assuming, however, that it is possible to work out a plan whereby we get the minimum number of examinations that are necessary and we make some saving in money, we reach another stage—the problem of the examination itself.

## Some Examinations Too Narrow

In that work, as we all realize, there has been, in the past, a great deal of money wasted from making too narrow an examination. A specialist in a particular direction looks for that particular thing and in a good many cases properties have been turned down and sometimes development has been poorly started because, for example, the specialist did not have adequate knowledge of the geology of the district. To illustrate, an examination of placer ground with a view to dredging should take into account some knowledge of the physiographic history of that region, because that is a very important factor in the possibilities of the accumulation of gold for placer, and also in certain of the copper properties.

We have not always, as engineers, taken advantage of the information that is available along that line. We are not as familiar as we might be with the results that our associates, working a strictly scientific field of work with the geological surveys, state and national, have obtained, which bear upon that problem. If we could think from a little broader point of view, I believe it would often be helpful and would perhaps help to bring in new properties.

There is one other phase of waste in connection with this matter of development of properties that is very much to the fore now. The development of properties upon the public lands of the West has been in the past

* Address at Joint meeting of the Mining and Metallurgical Society of America and American Institute of Mining and Metallurgical Engineers, Feb. 22, 1922.

Digitized by Google

through the process of location and doing or not doing assessment work up to the point of patenting or selling the claim to some one who will take it up on behalf of the company. All who are familiar with the West know that, in a large way, that assessment work has been a farce. Very often it has been done in places where it has simply meant an expenditure of money and has brought no practical results; and yet there is a widespread feeling throughout the West, and a feeling that I find some of the engineers who act as scouts can sympathize with, to the effect that it is only by miscellaneous digging around over the country that mines have been found in the past and that through that same process we may expect to find them in the future.

### Best Practice Needed Everywhere

My own feeling is that the time has come when we should take serious thought of this, and determine whether that system of prospecting is going to be as valuable in the future as it has been in the past; and whether we have not got to develop some different methods so that, for example, the man who is a claim owner may, if he wishes, instead of doing prospect work, put money into it and find whether it can be used in some other form, for the benefit of the district. This is one of the proposals in the bill for the revision of the mining law which is now before Congress; and I may say, incidentally, it is one of the proposals that provoked the most outcry in the West. The individual prospector has got it into his head that it is going to interfere tremendously with his prosperity and happiness, and I believe it is a thing of sufficient importance to warrant the attention and some of the energy and thought of the engineers of the profession.

There is still another stage in which waste enters into this field. The Bureau of Mines was established with the idea of increasing safety and decreasing waste in the mines, and when the first appropriation was made, for studies in miscellaneous resources, Doctor Holmes employed Professor Parsons to make a general summary or review of the waste in the mining industry. I have not those figures at hand but they showed an enormous amount of waste in the little industries of the country—the non-metallic industries which are largely in the hands of people of small capital, of small experience, who are not capable, perhaps, of organization into such big units as copper mining, for example. There is a tremendous waste in all of that field and a good deal can be done. If we could get everywhere in the mineral industry the best practice that is now in the mineral industry, we could make an enormous saving both of material and effort and energy.

There is a tremendous amount of good that can come, too, from spreading out into one branch of the mineral industry the knowledge that exists in the other branches. We had an example of that this year in some work done by the Bureau in coöperation with four of the big brick manufacturers' associations. Brick is one of the materials of which the price has not come down and an effort was made to find out, if possible, some way of reducing the cost to the manufacturer without throwing the reduction altogether upon labor.

The two big elements entering into the cost of brick are labor and fuel, so that the natural point of attack was fuel. With this general problem before us, we put into the study of the brick industry some of the men from the Fuel Division who had done such long and successful work in the study of combustion problems in steam-boiler practice; and as a result of the first investigation, which was made at a brickyard, it was found that it would be possible to decrease the amount of fuel used in that particular yard by 140 tons per month. In a general way, in the three big yards that have been tested, it has been shown that it will be possible to cut the fuel consumption about one-third, the time of burning substantially the same amount and, in two out of three cases, to improve the quality of the product.

That was merely a matter of bringing into one branch of the industry the knowledge already available in another branch of the industry; so that we come back to the thing that as engineers we so often have to think of, and that is, the biggest waste of all is the waste of technical knowledge. Every time we bring technical knowledge out of its hiding places and make it available to the whole industry, we have done something of benefit to the industry.

---

## A. S. and R. Wage Analysis

A WAGE analysis of the American Smelting and Refining Co. (U. S. plants) for the year 1921 shows that readjustments produced further slight decreases in the December, 1921, rates of pay compared to November rates, but the wages paid were, in December, still 65 to 66 per cent. above pre-war rates.

Indicating how labor costs were factors in increasing the cost of production, the analysis shows that, in 1914, repair, supply and construction labor was paid an average of $2.42 for an 8-hr. day, while in November, 1920, the rate was $5.39, an increase of 123 per cent. The rate for direct operating labor in 1914 was $2.02 per 8-hr. day, but in October, 1920, it had risen to $4.55, an increase of 125 per cent.

In December, 1921, through various readjustments, the rates for repair, supply and construction labor had been reduced to $4 for an 8-hr. day. This was a decrease of ½ per cent. compared to November rates, but 25.9 per cent. below the highest rate, $5.39, paid in November, 1920.

Similarly, the rate of $3.37 in December, 1921, for direct operating labor was 1.1 per cent. below the November rate, and 25.9 per cent. less than the record rate of $4.55 for this class of labor in October, 1920.

# Factors in Mine Management That Lead to Loss and Waste*

By POPE YEATMAN
Consulting Engineer, New York City

THE Committee on the Elimination of Waste in Industry, of the Federated American Engineering Societies, in its report says that "Waste in industry is attributable to four causes:

1. Low production, caused by faulty management, of materials, plant, equipment, and men;
2. Interrupted production caused by idle materials, idle plants, and idle equipment;
3. Restricted production intentionally caused by owners, managers, or labor;
4. Lost production caused by ill-health, physical defects and industrial accidents.

The committee sent out elaborate questionnaires, and in them divided the responsibility into Management, Labor, and Outside Contracts. These questionnaires showed that in the different industries examined the responsibility of Management was from 50 to 80 per cent. and of Labor from 9 to 28 per cent. The percentage of responsibility that Management was held accountable for was much larger than any of us supposed. However, when this question is studied, we realize how necessary it is to select, in the first instance, suitable personnel, in the form of directors, managers, heads of departments, experts, etc.

We would like to believe that the percentage of responsibility of Management for waste in the mining business was less than that quoted above, but there are so many mining properties started up and operated by men of no experience in such lines, and there have been so many improvements in late years in mining and metallurgical methods not taken advantage of, that we can not believe that the percentage will vary much from that already quoted.

Quoting from a report approved by the Committee on Management of the American Society of Mechanical Engineers:

Management is the art and science of preparing, organizing, and directing human effort applied to control the forces and utilize the materials of nature for the benefit of man.

When we speak of management, we have in our minds one person or one directing authority. In reality, however, except in the case of a small property owned and worked by one individual, the management consists of a number of individuals, and the conduct of operations is not alone in the hands of the manager, but is carried out by a rather complicated system, starting with the president and board of directors, with perhaps an executive committee and departmental heads, followed by manager, sub-managers, superintendents, and foremen, and it is due to this ramification and division of authority and responsibility that great wastes, not usually considered or in general not noticed, creep in; and it is against waste due largely to the lack of proper functioning of the organization mentioned that this paper is directed.

The ordinary wastes about a mine are ever present and are too well known to anyone in charge to warrant more than passing notice here. They are in connection with excessive or improper use of powder, leakages of air, loss of tools, lack of care in keeping up repairs, insufficient trackage, improper planning resulting in too few working faces for the tonnage desired, poor service for transport of men into the mine and to faces, insufficient ore bin capacity, resulting in tie-up of tramming, poor light, lack of supplies and poor delivery of same, and bad supervision, to say nothing of choice of inadequate and inefficient machinery.

In the case of steam-shovel mining, in addition to some of the above, wastes occur due to lack of motive power, tracks, preparation for and blasting in advance, proper facilities for repairs, and for delivery of fuel, water, etc.

To insure the proper operation of a mining corporation of considerable size, there should first be a board of directors, made up of men of energy, high standing, and business ability, and they, and especially the president of the board, should be able to give the business the attention it demands. The acts of this body should, in the main, be legislative rather than executive. It should pass on the policies of the company, attend to the finances, and keep in touch with the actions of the manager, who should be the administrative head and be held absolutely responsible for the conduct of operations. The duties of the president of the company are, also, more or less executive in nature in his dealing with the manager, and with outside interests, such as legal and financial.

For quick action, an executive committee of the board is often advisable, but it should in no way usurp the administrative or technical duties of the manage-

* Address at joint meeting of Mining and Metallurgical Society of America and American Institute of Mining and Metallurgical Engineers, Feb. 22, 1922.

Digitized by Google

ment. The great trouble in administrative work by a committee is the dodging of responsibility through the spreading out of authority and the feeling that praise or criticism would be divided; also, in the case of criticism, the feeling that it would be passed on to the management.

A bad start by the board of directors at the beginning in the way of poor financing, bad planning, etc., may cause such waste as to handicap a venture, in spite of a good management that may be in charge of the operations.

The board of directors, after choosing their manager, must place their full confidence in him and back him up to the fullest extent. If confidence in the management is weakened or destroyed, a change should be made immediately, for even a good manager cannot "carry on" to advantage where there is a lack of trust, and under such circumstances a change would be best for both the directorate and the management.

As it is found necessary to have financial auditors to verify accounts, so should there be occasionally an independent technical audit of the administration of operations by some expert, not because there is a lack of trust in the management, but as much as anything else to prove that the board's approval of its manager is properly based. Such technical audits have been rare in the past but are of great value. Too often it was taken for granted that operations were being well managed if the returns were satisfactory, and on the other hand that if the returns were poor necessarily the management must be poor.

Trust and faith in the management is the essence of coöperation between the manager and board of directors, and without coöperation no really good work can result.

## Financing

Censure for an unsuccessful or badly managed operation is too often placed upon the manager, when in fact the fault lies in the home office. Under-financing and over-financing are often to blame. Under-financing makes it impossible to carry out necessary improvements looking toward the elimination of waste due to low extraction, or to wornout or antiquated machinery, such a course resulting in not only non-conservation of resources but also smaller profits than the proposition deserves.

Often, too, with a company that has been operating successfully for some time, the directors are unwilling to lay aside funds for improvements, insisting upon keeping up dividends or adding to them.

Over-financing may result in waste from too heavy overhead costs for interest, to the installation of a plant too large to be warranted by the size of the property or to the impossibility of working it on the scale that the plant calls for. Most of us have seen the building of smelting or treatment plants for mining operations before the ore deposit has been proved, and such wasteful use of funds has by no means necessarily been done for stock-jobbing purposes, but simply on account of poor business judgment.

## Equipment and Overhead

Waste in connection with equipment is to be considered in a paper by Mr. Ingalls, so I shall not dwell on that phase any further.

The refusal to sufficiently equip is often equally disturbing. What could the low-grade porphyry mines accomplish if attempts to equip and operate them on a scale of less than a thousand tons a day were made? Their success has been due to large-scale operations, without which many of them had already proved failures.

Refusal on the part of the directors, although advised by the management, to install for the treatment of gold ores a cyanide plant; or in the case of many copper, lead or zinc ores, an oil flotation plant, has resulted in much loss due to low extraction and consequent loss of added profits.

The board of directors is to be blamed for increasing unnecessarily "overhead" due to extravagance in office expense, head office staff, employment of unnecessary experts, expenses in travel, etc.

## Employment of Experts

While the employment of experts in certain special lines is often most desirable, it is frequently unnecessary and wasteful. Except in the case of a technical audit, reports by such experts should be made directly to the manager for his consideration and advice.

Too often the expert makes his recommendation on his own particular specialty, without considering the effect on other dependent operations. The dovetailing of the different operations and making each one serve its purpose towards the achieving of the best results is one of the principal functions of the manager.

We know of so many instances where the improvement in costs and increase in savings in one department has been at the expense of others, and where the loss in other departments has been much greater than the gains in the first, and here we can see the bad features of dividing a business up into departments which report directly to the directors rather than to the manager—the head of each department trying to accomplish the best results for his own section and not giving due consideration to the others, all heads being ambitious, having knowledge of their own work, being anxious for the success of the organization, but working as independent units and not being in a position to merge the more or less conflicting interests.

Instances have been known where enormous expenditures have been made in deference to the suggestions made by experts, in which most elaborate plants have been installed, such plants being laid out far in excess

Digitized by Google

of the needs for other operations on which these were dependent. This illustrates a lack of coöperation and a lack of sufficient power given to the management to properly dovetail the different requirements so as to produce a more homogeneous whole.

### Decision as to Size of Plant

One of the most important questions, and for which the directorate is very largely responsible, after receiving trustworthy advice as to the size of the orebody, probable operating costs, etc., and recommendations as to size of plant and physical possibilities of operating, is to decide on the size of the installation in order to obtain for the stockholders the greatest profit, and in this connection the so-called "present value" has to be considered.

Other things being equal, it is possible to make practically the same total operating profit if a property has a life of one hundred years as when the plant is installed for working out the orebody in thirty years, but in the case of the shorter life the "present value" far exceeds that of the more extended operation.

On the other hand, a plant may be installed so large that the extra expenditure to be incurred may make the "present value" less than in the case of a smaller plant.

Assuming a property having 400,000,000 tons of ore developed, on which $2.50 per ton operating profit could be made with metal at an average price; the "present value" of the ore developed would depend on the size of the treatment plant. The following table shows the great difference in the "present value" of such a property with different assumed plant capacities, all other factors being the same:

| Daily Plant Capacity | Life of Property | Annual Operating Profits | * Approx. Present or Actual Value |
|---|---|---|---|
| 10,000 tons | 111 yr. | $8,750,000 | $109,000,000 |
| 20,000 tons | 55½ yr. | 17,500,000 | 209,000,000 |
| 30,000 tons | 37 yr. | 26,250,000 | 292,000,000 |
| 40,000 tons | 27¾ yr. | 35,000,000 | 359,000,000 |
| 50,000 tons | 22¼ yr. | 43,750,000 | 411,000,000 |

It will be seen from these figures that in cases of mines with great ore reserves, there may be great losses to owners if plant capacity is not great enough. Also, that cost of increased plant would be small as compared with increased value obtained.

### Indecision

Among the common faults of a board of directors, which cause loss and waste, may be mentioned indecisiveness and vacillation, which tend to discourage the manager and his staff, and often times mean great delay and the expenditure of unnecessary funds; also lack of careful consideration before making decisions as to method of operation of changes in plans leads to waste. Cases have been known in large operations where the question of method of mining was under consideration for six or seven years. First, it was decided to carry out one method; then it was held up; again decided; and again held up, much to the detriment of the operations, which should be planned several years in advance and carried on with some definite object in view, the lack of which not only upsets the organization but, if a change is finally made, will have resulted in considerable loss. It goes without saying that propositions should be carefully considered, looked at from all possible points and discussed freely, but after this has been done decisions should be quickly made and lived up to.

Frequently, too much time is taken before deciding on methods, or plant design, or changes in same, and too much conservatism is shown in unwillingness to change antiquated methods and spend money for improvements.

### Unnecessary Detail

It is necessary to mention a not too infrequent trouble and expense resulting from the often inconsiderate request by directors for complete plans and estimates, and for numerous and very detailed reports on certain phases of the operations. I have known of hundreds of thousands of dollars being wasted on account of demands for plans and estimates for plants of different capacities, where the general questions under consideration in no way required any such elaborate details at such great expense. It is indeed wise that the directors should be kept fully informed, but the continual request for information in detail, which requires the collaboration of different heads of departments and takes them away from their operating work, is not desirable. It is often due to the thoughtlessness of directors and non-appreciation of the work entailed, but when carried to an extreme it is a wasteful and disturbing method.

### Non-interference

Too much emphasis cannot be placed on the non-interference by the board of directors with the operating management; nor should the board of directors try to influence the manager in the appointment of his staff or employees.

There are a number of splendid examples, in this country, of the proper functioning of boards of directors and managements, and to such coöperation has been largely due the great success of the undertakings.

### Loss and Waste due to Manager

The possibilities of losses and waste due to executive or administrative control are so great that the choice of a man for the position of manager must be made with the greatest care, and, regardless of suggestions or advice from experts or consulting engineers, the responsi-

* Note.—Present value figured on an 8 per cent. dividend basis and on the amortization fund being reinvested annually at 5 per cent.

Digitized by Google

bility for the control and operation of the mining property must devolve upon him.

It goes without saying that the manager should be honest, industrious, intelligent, energetic, able and with initiative and a sense of responsibility. He should know how to select and handle men, how to instill loyalty into the organization, and how to keep up with the advances in improvements. He should above all have a technical and commercial knowledge of mining. The choosing and the responsibility for such choosing of departmental heads should be left to the manager, and those departmental heads should be directly responsible to him for their organizations, and for the superintendents, foremen, etc., under them.

The feeling of responsibility should be appreciated all along the line. The question of loyalty and esprit de corps is most important, and it should be understood that loyalty to the chiefs should mean at the same time loyalty to the company as a whole.

While the manager should be able to understandingly supervise and correlate all the departments, he should also be able to so use his staff as to make it possible to give a general supervision of the operations as a whole, and not be tied down by such detail as would tend to swamp him. There are many managers who in small operations prove excellent, but because of not being able to delegate authority, prove almost worthless where such operations become extended.

As far as the direct management is concerned, as a general rule the larger organizations are being handled by high-grade technical men of great ability and experience, whose operations have been conducted with great efficiency. In fact, many of these men might be considered efficiency engineers in the true sense.

In commenting on the question of waste, the Committee on the Textile Industry of the Committee on Waste in Industry, makes the following wise statement:

> The placing of the responsibility for waste, however, is in some respects the least important phase of the problem. The causes of waste and their elimination are the vital elements of the situation. If they can be determined, in some degree at least, and ways and means found to overcome them, then this investigation may be said to be truly worth while from a constructive standpoint.

It is ever the problem of the manager and his staff to find out where the wastes are and to determine some method for their elimination.

Among the causes of waste in management may be mentioned indecisiveness and vacillation, also mentioned in the case of the directors.

## Methods of Mining

Great losses may occur through the choice of a method of mining not best suited for the orebody in question, and on the proper choice may even depend the success or failure of the operation. Decision has to be made in the case of large orebodies as to whether steam-shovel or underground methods should be employed for the extraction of the ore, or as to which one of several caving methods should be introduced—whether top-slicing, sub-level, or block-caving, or modifications of the latter, such as shrinkage stoping and caving of the pillars; the Ohio system, or some one of its modifications, such as the Ruth, Miami or Gastineau.

With a low-grade orebody of great size, other things being equal, the lower costs of a method like the Ohio, or some one of its modifications, would more than counteract the loss of ore due to the admixture of waste and ore that is bound to result from the use of this method.

In the case of a higher grade ore, though entailing a greater mining cost, the choice of the sub-level or even the top-slicing system might be advantageous, because of increased profits due to less admixture of ore and waste, and to the reduction in loss of ore which results from the employment of either of those methods.

In the case of flat veins, choice has to be made of the longwall or pillar-and-stall systems; or in the case of veins of considerable pitch, the question of back-stoping, underhand stoping, shrinkage stoping, filling or square-setting, or other styles of timbering, has to be decided, and on such a decision much depends.

## Plant Design

It is always a temptation on the part of a manager to have as fine a plant as possible, not only for accomplishing good results but for appearance as well, and over-expenditure in equipment and plant has to be guarded against. He has also to guard against the requests and demands of department heads for improvements in their special lines for the same reason, and must carefully weigh the recommendations made by heads for outlay intended to diminish costs or improve extraction in their special departments, especially if such reduction in costs produces greater costs in other departments; or where it is a case of obtaining greater extraction, he must see that the cost of obtaining this is not greater than the profits accruing by such changes. While the desire to increase extraction and decrease costs of operation is always laudable, still there is often the danger of the capital outlay being greater than the saving resulting. In other words, often the operating costs in obtaining such improved extraction are greater than the value of the increased extraction.

Very often figures are given which prove that by the introduction of additional machinery or of a new process, the extraction can be increased, and the fact is lost sight of that by so doing the profits would be decreased rather than increased, or that the additional saving would not cover the cost of the installation.

The question of the location of the different plants for carrying out the operations has to be carefully considered. It is well understood that, as far as possible, the different plants should be placed close together, but questions of supplies, water, space for

Digitized by Google

plant, transportation, etc., often make it necessary to have the mining operations carried on at one place, the concentration at another location, and the smelting at a third, and it is in deciding upon these points that the management, whether it is the manager himself or the consulting engineer, who may have charge of the preliminary design and laying out of the operation, must be most careful.

Instances have been known in which, if only the concentrator were considered, the lowest costs for concentration would be obtained by placing this plant at a certain location, but when the transportation of the ore to that place was considered, it was found much more economical to place the plant near the mine.

On the other hand, favorable transportation costs with the concentrator near a water supply would make it advisable to locate the concentrator or smelter at some distance from the mine.

The departmental head, left to himself and thinking only of his own costs and advantages, would be inclined to consider his own particular problem by itself, rather than as a question of the whole.

### Losses Due to Choice of Methods

We all know the great advances made in concentration due to oil separation. On the other hand, we also know that the use of flotation processes on some ores at certain properties, while it has increased the extraction, has done this at a cost greater than the extraction warranted, and that in so doing waste in profits has resulted.

Backwardness or over-conservatism on the part of the management in recommending improvements has resulted in operating at a loss in extraction and profits that is unpardonable.

A great temptation to any management is to reduce costs, and to do so is a laudable ambition, but the attempt often results, as will be shown, in a reduction of profits instead. For instance, in the mines of the Rand near Johannesburg, in South Africa, the gold occurs in reefs of varying thicknesses. Within certain limits, the wider the reef or the greater the thickness of ore mined, the lower will be the cost per ton of ore extracted. On a five or six foot reef, other things being equal, the cost per ton of ore extracted is lower than in the case of a reef of nine or ten inches. The narrow reef is, however, as a rule very much higher grade per inch of thickness than the wider reef, and for the best profits it is advisable to stope as narrow a working face as possible, for the reason that while the material outside of the reef itself is almost barren and that one can sort out barren waste pieces, still in the breaking of the waste much of it is too fine to be picked out and necessarily goes into the bins with the ore, thus diluting the latter and not only adding to the tonnage that it is necessary to mill, and therefore adding to the cost per ton of ore, but also resulting in lessened extraction due to the fact that as a rule the tailings from the combination of waste and ore will run very nearly the same as would be the case with the treatment of the higher grade product.

The mining, however, of this narrow vein is more costly, and therefore on the books it shows that the cost per ton of ore mined is higher than in the neighboring property containing the five or six foot reef. The tendency of the directors is to hammer the manager and insist that he mine as cheaply as his neighbor, and yet in carefully sorting and mining as narrow a face as is compatible with proper working, the manager is carrying out the work to better advantage to his directors and stockholders than if he tried to make an individual record of low costs in mining. This pressure on the managers has been very great and many give way to it because of the continual criticism, and perhaps due to direct orders, in spite of the manager's explanations of the advantages and greater profits to be derived by the method carried out by him.

Another illustration might be given in the case of the development of low-grade copper ores, where in addition to ore of good grade, much larger tonnages of low-grade ore, either on the edges of the deposit or in greater depth, have been encountered. This latter ore, when averaged with the higher grade ore, would show a tremendous tonnage of payable ore, but a large part of this tonnage would hardly be payable and would add little to, if not lower the "present value." The mixing of such tonnage with more profitable ore would either require a much larger plant, or with the same plant would result in lower annual profits than would have been received had the better grade of ore only been worked.

Still another illustration might be given in connection with underground mining of a very wide deposit, in which the more profitable ore was on the hanging wall side and gradually decreased in value into the foot wall, until it fell considerably below what was considered of "pay value." Physical conditions prevent the very great enlargement of the plant. With a plant of the size proposed the time necessary to extract the ore would be nearer a hundred years than it would be fifty. It would be possible to extract the ore from the hanging-wall side and make great annual profits, and to leave most of the ore in the foot-wall side to be extracted at some future time, after, say, fifty years.

The inclusion of the low-grade ore with the high-grade would show a very great tonnage of recoverable copper, and yet the mining of this would give the stockholders during the next thirty or forty years very much smaller profits than would be obtained if the operations were concentrated on the better grade ore.

On the other hand, we know of many mines where "selective" mining has been carried on to the extent of what is called "gouging" or "picking the eyes" out of the mine. In so doing, ore is left of lower but still good grade which could have been mined at considerable

Digitized by Google

profit, but which so far as the future is concerned is practically lost. We also have many instances in old mines in Mexico, in which ore which was at that time profitable under the method then employed had been extracted, but the ore left, and which could not be profitably treated under the methods then in vogue, can now be extracted under improved methods, and many old fills and portions of then unprofitable veins are now being mined. The former workers were not in error in leaving such material, because it would not have given a profit to them at the time.

### Not All Waste Reprehensible

Another illustration of waste which was not altogether reprehensible was the mining and concentration of zinc and lead ores in the Joplin District thirty years ago. At that time, the camp was a "poor man's camp" and prospecting was done with little or no capital. If ore was found, it was first treated at a low extraction with hand jigs, and later perhaps a small concentrator was erected. None of the mines was large enough to warrant expensive plants or the installation or operation of machinery for higher extraction. For these small companies a concentrator built with the necessary provisions for a high extraction would probably not have enabled the original owners to come out even. The deposits at that time were small and erratic and it was better business, though not highly commendable as a conservation measure, to run with high losses rather than with higher extraction, with the aim of greater profits in view.

Many managers are too prone to try new methods without their being thoroughly tested out. A desire to improve is certainly to be commended, but care must be taken not to rush in too soon. On the other hand, too great conservatism is to be deplored.

### Progressiveness but not Overdevelopment

It is within our experience that there are companies which have been models of progressiveness and have been leaders, and which have grown complacent and satisfied to let well enough alone. This continued so long that they fell into the rear, until by some shock their eyes were opened, as for instance by knowledge of the great strides made by some other mining companies, causing the former to wake up and to introduce needed improvements and renew the progressive movement. Another reason for the discontinuance of a progressive course is the feeling on the part of the directors that a great deal has already been spent for improvements and that a halt should be called, and natural inertia makes difficult the return to motion or advance.

Losses or wastes often result from over-development. It is a great satisfaction to any manager to have a knowledge of what is before him, of the tonnage that may be expected to be available, and to be able to average his ore rather than to have periods of high-grade followed by periods of low-grade ore. Where an amount of ore has been developed in excess of requirements, a further opening up of ore becomes more or less of a luxury, being unnecessary and requiring considerable expenditure far in advance of requirements.

In the case of many vein mines, however, where the ground is soft or heavy, such for instance as the mines around Bisbee or Butte, and where the development is done mainly by drifts, crosscuts and raises, it would not be the part of wisdom to over-develop, because of the cost of keeping open the drifts, on account of deterioration of timber from rotting or crushing. The cost of keeping up this work far in advance would be greater than the advantages obtained.

In the case of iron ores or the low-grade porphyries, where the testing of the orebodies can be done by churn or diamond drills, it is very often desirable to determine the limits of the orebody in order to decide on the proper sized plant for the treatment of the ore at the best speed that financial or trade conditions would warrant, but even here development can be carried further than necessary and in too much detail, resulting in excessive expenditure.

### Accounting

In determining and avoiding waste, besides constant supervision and testing, careful and very detailed accounting is required,—much more elaborate than that required for annual financial statements and balance sheets. Without such close accounting the question of leaks or improper operation often becomes a guess and results in numerous debates difficult of determination. We have what we call bookkeeping or cost accounting for the management, and bookkeeping for the home office. Except for the conclusions, the bookkeeping for the management is too voluminous and exhaustive for the home office, and the accountants of the home office often object because of what to them appears unnecessary detail.

Of great if not equal importance to the cost accounts and technical records are the sampling and metallurgical records.

For a manager who will really study the cost sheets, the details are necessary and illuminating, for they allow him to place his finger on weaknesses that would otherwise be difficult or impossible to detect.

### Size of Staff

Research work must be kept up, in order to discover losses in extraction or operations and to improve conditions. Such work can be overdone and its cost exceed the gains, but it should be carried out in reason, and even on a small scale should reap valuable results.

In the actual operations the great considerations are loyalty, coöperation between the departments, teamwork, and a feeling of trust on the part of the

Digitized by Google

employees due to fairness and sympathy on the part of the management. The great destroyers of good work are jealousy, ambition for self at the expense of others, and a feeling that someone else's gain is your loss.

The temptation to have too large a staff is often great and should be avoided. At the same time, it is dangerous to cut it down too low. One of the great difficulties in any organization is to build up a force in which there are understudies for all the important positions. The old Cornish superintendent was always afraid that a good man might displace him and step into his shoes, and this feeling is common with a great many managers and heads of departments today. A manager may feel a little more secure in his position if he has no understudy, but it is not for the best interests of the company. He should make his men feel that he is looking after their interests, and he should arrange for the promotion of his own men, either in or out of the organization, as rapidly as possible.

A very common trouble with old-time managers has been the using of machinery or methods of their own design or invention, rather than the adoption of better methods designed by someone else. Another common failing on the part of managers is the overdesire to be popular with their men and to allow too many perquisites to the employees, which unnecessary allowances are quite often next to impossible to abolish and result in not a little loss to the company. The abuse of such privileges almost always leads to trouble.

### Stocks of Supplies

One of the great causes of loss in carrying on operations is the temptation to carry too large stocks of supplies, and this temptation becomes greater as the distance from market increases. The carrying of heavy stocks of supplies locks up funds unnecessarily, and results in having too much dead stock on hand as changes or improvements in methods are introduced. It is indeed a dreadful thing to run out of necessary material and have to stop any part of the work that is essential. It is often thoughtless and unreasonable, however, on account of the fear of this to carry too heavy stocks.

### Loss of Time Through Shutdowns

Loss of time through shutdowns is the bugbear of any mining operation, and causes losses that are often difficult to gage. If a shutdown becomes necessary for a short time, many costs, such as overhead, continue—water has to be pumped perhaps, machinery kept in order, watchmen on the job, and interest and salary charges are ever present. If the shutdown is for a long time, it may mean the dissipation of employees, and later the gathering together of new men and the building up of a new organization, making the "turnover" more costly even than the ordinary during the operating period when a "turnover" of greater or less extent results from the discharge or voluntary leaving of some men. This labor "turnover" in any business is a very serious matter and adds greatly to costs.

In starting a new mining camp, such "turnover" reaches the maximum, for the "floaters" come in from all directions and it takes some time to accumulate a permanent lot of employees.

Shutdowns on account of labor troubles are frequently the cause of great loss. They may be brought on by the employees themselves, or, as is frequently the case, by outside labor organizations entirely, but in districts not under the control of labor unions the personality of the manager often prevents such difficulties, for in mining as in any other business personality is a great factor.

### Controllable and Uncontrollable Shutdowns

Shutdowns due to lack of orders or inability to dispose of the product are beyond the control of the local management. This is largely a financial matter and one to be determined by the board of directors. For instance, in the copper and zinc industries especially, it has been found necessary to shut down many properties or to curtail the production in others. The wisdom of this in many cases is subject to debate. In a property which cannot sell its product at a profit, a shutdown becomes necessary, unless it is thought that an increase in price sufficient to permit profitable operation can be expected within a short time. Even during a shutdown expenses are great and considerable loss results, for there are always overhead charges to be considered.

The shutting down of properties which can, even at a very low price, produce at a profit is a questionable one, for besides the cost of the shutdown and the difficulty and expense of gathering together a new organization when starting up, there may rightly be considered the loss due to no profits. It is a very questionable matter whether it is best by restriction of production to try to keep prices up so that high-cost producers can operate, and, in order to do that, have the low-cost producers shut down or curtail their operations. This is especially so with properties which have such large orebodies as to insure a very long life. Such a loss of profit is like a lost opportunity, not to be recovered, at any rate not during our lives. Is it best for the industry and for the state that such an artificial condition be permitted, which would allow the high-cost producer to operate when the low-cost producer can supply the demands of the public and at a reasonable profit to himself? I doubt it.

In connection with shutdowns, I have not considered the question of seasonal operations common in the coal and iron mines, or of placer or dredging operations carried on in regions of severe cold.

Steady and continuous operation of mines, mills, and transport service between the two, is the basis for

Digitized by Google

successful working. A delay in one department because another cannot receive the ore, or on account of bins being filled, or because of a lack of ore, increases cost and upsets organization. There must be a proper balancing and correlation of operations.

### Transportation

The question of the price for transportation by railroads is an important one, and one in which it is often possible to avoid great losses, either by careful routing, proper classification, or by a special arrangement through the federal or state railroad commissions for special consideration. In the old days much could be done in the way of working one competing line against another to lower railroad rates. This is still possible with water and other means of transportation. Even with the regulation of railroad rates at the present time, the question of transportation is so important that many of the large corporations have their railway departments to take charge of proper routing, tracing, etc. Where shipments are large and continuous, the question of getting cars is an important one, for without a proper and steady supply the mining operations cannot be carried on to best advantage. Any interruptions in the regular operations, through delays from whatever cause, are always costly, and this is especially so where, owing to the large scale operations it is not possible to keep large stock piles or ore bins, and dependence is placed on the continual supply of cars for the disposition of mine products. This applies particularly to the mining of coal and iron ore, and to a less extent to the shipment of concentrates or sorted ore. In the case of the low-grade porphyries the shipment of the raw ore is usually over the company's own railroad.

### Purchase of Supplies and Sale of Product

A common source of loss is in the purchasing of supplies. With large corporations this is placed in the hands of a purchasing department, whose sole business it is to keep in touch with markets and make the best bargains possible, but for proper work coöperation of the management is very essential. The tendency of the purchasing department is to buy as cheaply as possible, some times at the expense of quality or efficiency, and also to buy in larger quantities than may be warranted. On the other hand, the manager may hamper the purchasing agent by calling for goods of a special make when others may be equally acceptable, or he may too greatly limit his specifications.

With small properties, however, the manager may have to be his own purchasing agent, and he is often at a disadvantage because of being distant from cheap markets, buying in small quantities, or being interested in direct operating and technical problems rather than in strictly commercial matters. Pressure too, which, however, should not be given way to, is often brought to bear by directors or other stockholders to favor certain firms, who take advantage of such preference. It is because of such practice that the law against interlocking directorates has been found necessary.

Great losses often occur in selling the ore, concentrates, or metal produced. Large corporations have their own selling departments, conducted by experts in the business, who watch the markets and keep in close touch with the consumers; or arrangements are made by the directors with selling agents, whose business it is to watch the markets and make the best arrangements possible.

In the case of a mine whose product is metallic gold, there is no especial difficulty, as the United States Government is the purchaser at a fixed price. In the case of ores, however, it is often necessary to contract with a smelting company, and the arrangement of such a contract requires great skill and knowledge on the part of the management, for the reason that there are so many different bonuses, penalties, various smelting charges, etc.

The system of purchasing non-ferrous metal ores by the smelting companies is unnecessarily complicated, and because of this not fair to the inexperienced miner.

### Summary

To sum up: in addition to the usual well known direct sources of waste in mining properties, and for which the management on the spot is responsible, there are even losses that may be traced to either the board of directors or to the manager, or to both, and such losses and wastes are in the main due to lack of or improper financing; excessive overhead; indecision in action; over-conservatism; unnecessary detail or lack of it; interference with management by directors; poor selection of method of mining; poor plant design; lack of proper touch with the business through poor costkeeping and poor technical records; inefficient purchasing of supplies; poor salesmanship in disposing of product, or negotiating smelting contracts; and last, but not least, losses due to lack of proper coöperation between directors and manager and between manager and staff and employees, for in the final analysis success in management is absolutely dependent on teamwork and the earnest, intelligent and loyal efforts of all concerned, from the directors to the lowliest employee.

---

## Conference on Commercial Engineering

THE United States Commissioner of Education is calling a second public conference on commercial engineering on behalf of a committee appointed by him to investigate business training of engineers and engineering training for students of business.

The conference will be held May 1 and 2 at the Carnegie Institute of Technology in Pittsburgh and will be open to the public.

# Elimination of Waste and Improvement of Efficiency. What are the Economic Fundamentals?*

By W. R. INGALLS
Consulting Engineer, New York City

THE main objective of everybody, individually and collectively as the people of nations, is to earn their living and improve the scale thereof as much and as rapidly as possible. We are able to earn our living only by working and producing. We are able to rise to higher standards of comfort only by increasing our production of goods, or diminishing the waste of those that we do produce, or both. This statement is trite. It is equally trite to dwell upon the importance of increased production to be derived from increased efficiency of labor and improved management; and the good results that would accrue to everybody if employers and employees would work together to secure the maximum of production at the minimum of cost. All of this is nothing more than platitude, to which every intelligent person subscribes in the abstract; but what concerns us especially, and what is neither so easy nor so understandable, is to translate the expression of the abstract principle into formulas for action.

The national net income obviously may be increased in two ways, or by both together. One is to diminish the waste of the goods that we already have made available. The other is to increase the supply of goods. Increasing the supply of goods may involve the elimination of waste, but a distinction is to be drawn between the waste of things that we have and the failure to obtain those that we might have.

If we limit the term "waste" to the careless and profligate use of the materials that have come into our possession, together with the absorption of labor in doing obviously unnecessary things; and if we characterize by the term "inefficiency" the failure to accomplish in our industrial operations the best of which we are capable, we shall create a distinction that will be promotive of clear thinking. In this paper I am going to deal with inefficiency, not waste, observing the distinction, arbitrary if you please, that I have made.

Without any doubt the greatest inefficiency that exists in our economic affairs is that which causes hundreds of thousands, perhaps millions, of men to be idle a good deal of the time. The major reasons for such idleness are two-fold. One of them is the consequence of what for convenience may be called business cycles, although I do not hold to the hypothesis of business cycles as it is now being rather widely expounded. That hypothesis involves the idea of rhythmic undulations due to causes unknown, but which it is hoped may be ascertained. The movement of business in waves up and down is undeniable, but that there are recurrences of cycles every so often is purely imaginary, I think. It is unnecessary to digress into that subject. The extents of the rises and falls above and below a median line undoubtedly is less than is commonly supposed.

## Normal Percentage of Employment

In ordinary times of good business there is a certain number of workers attached to our industries of whom perhaps 95 per cent. are occupied, the other 5 per cent. being idle partly from disability, partly from choice, for there is always a considerable number of workers who are habitually idle. Let us suppose that for one reason or another there develops an increase in the demand for goods and services, the percentage of employment may rise to 98, which would correspond with the conditions of a boom. During the war we went much farther than that, for with about five million men transferred from industry to the army and navy we compelled all of the habitually idle to go to work and we induced a larger proportion of women than ordinarily to enter industrial employment. On the other hand, if the percentage of employment should fall from 95 to 92 we should have the conditions of dull times; if the percentage should fall to 90 we should have great depression, accompanied by a good deal of hardship.

The figures that I am using are intended to be illustrative, rather than precise or even approximate, for in fact there are scarcely any statistics illuminating this very important subject. However, we may check up by reference to some of the scanty data. The year 1914 was one in which our industrial conditions changed

*Address at joint meeting of Mining and Metallurgical Society of America and American Institute of Mining and Metallurgical Engineers, Feb. 22, 1922.

Digitized by Google

from normality in the first half to depression in the second half, following the outbreak of the war. The number of factory workers in that year was about 7,500,000. In the month of maximum employment about 96 per cent. were at work; in the month of minimum employment, about 90 per cent. In 1921 we probably had about 42,500,000 workers, of whom about 6,500,000 were farmers, and about 1,000,000 were in governmental service, leaving about 35,000,000 in other occupations. The maximum estimate of unemployment was about 5,000,000, which would indicate about 14 per cent. idle.

Nobody appreciates better than myself the imperfection of these data, but I think that they are near enough to bring out the point that I am trying to make; namely, that the range between the zenith of industrial activity and the nadir of depression is comprised within a rather small percentage of the total number of workers. Diminution of this range, or rather diminution together with elevation of both the high and low points would spell increase in both economic efficiency and social happiness. Such an improvement is not outside the zone of reason.

We have another kind of inefficiency, which may be more important, though I hesitate to make a comparative statement about conditions that can not be measured, or have not yet been measured. I refer now to industries which are so badly organized, or which function so badly that the workers engaged in them, or attached to them, are able to work year after year for only a fraction of the time possible, irrespective of whether the general state of industry be feverish, normal or depressed.

The most noteworthy examples of such industries is bituminous coal mining, wherein the average annual employment is only 200 to 250 days per annum. There are about 700,000 men employed in bituminous coal mining, compared with about 150,000 in anthracite, wherein the labor conditions are much better. The building industry, which employs about 3,000,000 workers, garment manufacture and boot and shoe manufacture are also major industries that are characterized by short-time work every year. In boot and shoe manufacture the number of persons attached to the industry is about 225,000; in garment manufacture about 375,000.

According to the report of the Committee on the Elimination of Waste in Industry of the Federated American Engineering Societies, the average clothing maker is occupied for only 69 per cent. of the year (300 days); the average shoemaker only about 65 per cent.; the building-trade workmen only about 63 per cent. Other industries will be found no doubt to exhibit similar conditions. On the other hand, there are industries wherein the workers ordinarily find full time employment. Thus the copper, lead and zinc miners of the country commonly work from 300 to 310 days per annum, these branches of metal mining being well organized and excellently functioning. The men engaged in transportation, about 2,250,000 in number, experience little or no inability to work.

Among the industries that are characteristically of short time nature, in contradistinction to full time, it will be found that they are subject to the vicissitudes of the weather, to the vagaries of fashion and to the obligations of seasonal conditions. The builder is especially the victim of the weather. We may perhaps plan the prosecution of such work better than we have been doing, but nothing can obviate the fact that building is largely out-of-doors work and can not be done so well in the winter as in the summer. The clothing and boot and shoe trades are essentially seasonal and subject to the whims of fancy and fashion. We may argue that this ought not to be so, but our arguments will be futile so long as we ignore the human nature which makes them so. Anthracite coal mining is inevitably subject to seasonal conditions, just as is building, for we need more of that coal in the winter than at other times of the year. We may counteract this condition by maintaining production and putting coal into storage during the period of dull demand, which is in fact done on a large scale, but this does not meet the economic condition that the proper place for storage is where the coal is going to be used and our homes are not generally built with bin capacity for holding a winter's supply of coal.

### Producing Industries Overbuilt

However, we can no doubt by the exercise of thought and the improvement of industrial organization mitigate the evils resulting from seasonal conditions and by such mitigation increase the regularity and time of the work of the persons attached to these industries. But there is another cause of short-time work that has not heretofore been dwelt upon sufficiently although it is an underlying cause and may perhaps be the most important of all. This is over-capitalization, and by that expression I do not mean financial over-capitalization, but rather physical. Another expression meaning the same thing is that our producing industries are characteristically overbuilt. At the present time the overbuilding is stupendous, largely as a consequence of the war.

I have gone into this subject broadly in my book* on the "Wealth and Income of the American People." Here I shall do no more than summarize the position of the major mining and metallurgical industries as they were at the end of 1920, remarking that the position at the end of 1921 was not materially different.

In iron and steel we have a blast-furnace capacity for the production of 48 million long tons of pig iron per annum. The steel works have an ingot capacity for 52.5 million tons according to some authorities, 55 million according to others. The steel-plate rolling

*G. H. Merlin Co., York, Pa.

Digitized by Google

mills are rated at 6,700,000 tons and the sheet mills at 4,000,000 tons. The maximum pre-war production of pig iron in the United States was about 31 million tons and of ingot steel about 30 million tons. At present the capacity for pig iron, ingot steel and both plate and sheet is far in excess of any prospective requirement.

The capacity for copper production is without any doubt greatly overextended, but it is difficult to express this numerically as to the mines. They produced about 1250 million pounds in 1913 and about 2000 million at the maximum (in 1916). At the latter time their production was forced to a rate that probably could not be maintained long. The present mine capacity is probably somewhere between 1500 and 1800 million pounds.

Our copper smelteries, not including those of Lake Superior, have capacity for treating about 22½ million tons of ore per annum, but the quantity smelted in 1916 was only about 11¼ million tons. Our electrolytic refineries can turn out about 2750 million pounds of copper, while the Lake Superior works, the producers of Bessemer copper, etc. can easily give 250 million pounds in addition thereto. Of course our refining business is organized on the basis of treating a great deal of foreign material, but even so the present capacity is greatly in excess of any prospective requirement. Our copper wire, sheet and brass mills have present capacity for the manufacture of about 2000 million pounds of copper per annum, but the use of copper in the United States immediately before the war was only about 800 million pounds per annum.

Our silver-lead smelteries are capable of producing 560,000 tons of lead, while the non-argentiferous smelters are capable of treating 557,000 tons of galena concentrates per annum, producing 342,000 tons of lead. The maximum pre-war production of lead was 436,000 tons. The silver-lead smelting capacity is not really overbuilt to the extent that these figures indicate, for there is included a good deal that has become obsolescent by geographical changes, *i.e.*, failure of tributary ore supplies.

Among the lead manufacturers there is an excess of capacity, both in the white lead and blue lead divisions, an excess although the blue lead plants (sheet, pipe, shot, alloys, etc.) are reckoned only on the basis of one shift per day; if there be need, their operations can be doubled to a large extent.

In zinc there is huge excess both in mining and smelting capacity. The smelting industry, after discarding some of the ephemeral war plants, still had good capacity for producing 800,000 tons of spelter per annum. The maximum pre-war production of spelter was 353,000 tons. However, a large part of the present surplus of zinc smelting capacity is destined to be extinguished soon, if it has not been already, by the conditions of natural gas supply in Oklahoma. The zinc oxide plant of the country is not materially overbuilt if the automobile tire business should hold to its maximum, but that is pretty doubtful, and probably we shall discover that there is some excess above the coming requirement.

Our anthracite-coal mining industry is not materially developed beyond the requirements, if we may rely upon our coal-mining colleagues, but they tell us that the bituminous mines can do twice what they are likely to be asked for. Some recent testimony before the Committee on Manufactures of the U. S. Senate showed that in 1920 there were about 11,000 coal mines in the United States, controlled by 7000 operators, whereas in 1913 the total number of operations was only 5776. According to a recent estimate by J. D. A. Morrow, the present capacity of the bituminous mines of the United States is about 776 million tons. In 1913, they produced 478 million.

In brimstone the country has capacity easily to produce 2,000,000 tons per annum, with prospective demand for no more than 1,000,000 tons. In 1913 we made 2,235,000 tons of sulfuric acid (basic 100 per cent. $H_2SO_4$); in 1918, no less than 4,700,000 tons, and at the end of 1918 we had capacity for 6,000,000 tons. The maximum pre-war capacity for making caustic soda was about 300,000 tons; now it is about 600,000 tons.

### Industries Other than Mining also Overbuilt

When we turn to other industries we find generally the same situation. Among the major manufacturing industries there are one or two, *e.g.*, textile weaving, that appear to be in a good position, but on the other hand there are some, *e.g.*, automobile manufacturing (not to speak of shipbuilding), that are in a very bad way. The great mass of our manufacturing industries fall in between those extremes and in general are in an uncomfortable position as to being overbuilt. We should not, of course, essay to be precise in ratings under this head. Adequate attention to this subject has not heretofore been given and the data that are available are often of only a rough and uncoördinated nature. In mining and metallurgy we know that annual capacity is stated in terms of the 24-hr. day, but in other industries it is given on the basis of an 8-hr. or 10-hr. day and can be increased by over-time work. Next, there is often uncertainty as to what is first-class capacity and what is second-class, or emergency, capacity, and what should be included in an estimation of the total. Every industry is likely to have a considerable portion of its surplus capacity in the form of plant that is old and relatively inferior but not yet obsolete. Finally, there is the question as to how much surplus capacity an industry must have in order to function easily and be prepared to work under peak loads. Even apart from the latter consideration, there are few industrial plants that can be worked at 100 per cent. capacity year in and year out.

After the above matters have been taken into consideration and we have determined the specific capacity

Digitized by Google

of our industries, another line of thought pertains to the relation between capacity and the requirement for it. It will be agreed, of course, that the demands made during the war are no criteria. What then? The best guide toward a generalization that I can offer is pre-war consumption, say the average of three years, plus a percentage corresponding with the increase in population, and plus or minus a factor representing increase or decrease in the scale of living. This formula refers obviously only to those industries that are purely domestic. The population of the United States at the middle of 1913 is estimated to have been 97.3 millions. At the middle of 1922 it will probably be about 108 millions, or about 1.11 that of 1913. If, then, we were using 750 million pounds of a commodity in 1911–13, we should expect a use of about 832 million in 1922. We should probably say that the industry should have a 10 per cent. working surplus of capacity, or say an aggregate of 900 million pounds, and that if it had actually capacity for 1800 million it would be 100 per cent. overbuilt.

Lest this illustrative calculation be misinterpreted, let me say that it is my own belief that on the whole American consumption is now below the par of 1911–13 and that when we begin to build up it is going to be from a lower level than 1911–12, meaning, of course, a lower level per head of the population.

### Overexpansion a Consequence of War

Manifestly this is the broadest kind of a generalization and it is not to be applied indiscriminately to individual industries. Thus, no one would think of forecasting the demand for automobiles on the basis of 1913, for that industry has experienced its great growth since that time; vice-versa, as automobile manufacturing has waxed carriage building has waned. There are less spectacular cases of speeding up or lagging behind in individual industries; thus electrification has outrun other industries and we may foresee a continuance of its gain. On the other hand, the provision of railroad transportation facilities has lagged behind the general average.

However, the taking into account of all of these factors and conditions does not ameliorate the general conclusions that our producing industries, with but few exceptions, are greatly over-extended. The magnitude of the over-expansion is a direct consequence of the war. This is not a condition peculiar to the United States. It obtains, I believe, throughout the civilized world. From all that I read the position in Switzerland, Scandinavia, Spain, Holland and Japan is similar to our own. The countries that thought that the war was enriching them at the cost of others buried their new fortunes in factories, ships and other things that are now of no use to them. So with ourselves. We put billions into plant that in plain truth we must throw away and write off.

Yet, we can deduce from this a plain object-lesson. The demands of the war produced conditions in an exaggerated, even a grotesquely exaggerated, way that are developing all the time and induce what are called cycles in business. Broadly speaking, these result from miscalculations. It is found, let us say, that the supply of goods has not kept pace with the steadily growing demand. A rising market ensues. Haste is made to provide new plant with which to meet the demand. Again there is miscalculation. The demand is overestimated. Then there is collapse and depression. Much of the superfluous plant is allowed to rust and decay. While eyes have been blind and minds have been dull the time comes when there is shortage of supply again. Then the upward swing begins and history repeats itself. This is so trite that it is primer economics. Yet we dully abide by the principles of *laisser faire* in this, although we have repudiated that in other things. The consequence of *laisser faire* in this is that we are repeatedly building superfluous plant and eventually throwing it away. This causes an industry to be both over-capitalized and over-manned. On the down-grade the component parts of the industry struggle in a contest for the survival of the fittest. With substantially unchanged overhead expense, itself swelled by the boom, individual plants are operated at only partial capacity; and the enlarged personnel that has become attached to the industry is able to work for only part of the time. If the competitors are pretty evenly matched this condition may become chronic, as has been the case for many years in the bituminous-coal industry.

We can now see just these events crystallizing in a new industry, *viz.*, automobile manufacturing. There are more than 100 manufacturers, with annual capacity for producing 2¾ million cars, and they are still adding to capacity. Walk through any city and note the sales rooms, each with its own corps. I need not dwell upon what overhead means in this industry. There were made during the last year two careful, outside studies of the absorbing power of the domestic market for automobiles. One forecast was for 1½ million per annum; the other for about one million. What is likely to happen in this industry is pretty clear.

I need not elaborate upon the economic inefficiency, or waste, if it pleases any one so to call it, that results from overbuilding. Nor shall I seek to obscure the responsibility for it by attributing it merely to human nature. If we accept the generic division of the forces of production into capital and labor, the former is in the main the responsible party, for it leads while labor follows, blindly and helplessly. Yet labor is not free from blame inasmuch as there are important cases wherein industrial overbuilding is clearly attributable to the policies and actions of labor unionism. Thus, the manufacture of boots and shoes was driven from its primary centers in Massachusetts into the country regions of New England and then to places as far west

Digitized by Google

as St. Louis. At this moment shoes made in St. Louis are sold in Lynn under the very noses of the local manufacturers. Similarly was the book printing industry driven extensively from the large cities to suburban and country towns. Clothing manufacture which was centralizing in large factories in New York has been dispersed among a myriad of small shops. Such developments, under labor union pressure, spelled for these industries over-building, over-staffing, and over-manning, with the consequential evils of increased costs and short-time work.

In the exploitation of natural resources we are subject to the same broad economic laws that govern other industries, but we have the modifying, or disturbing, factor of treasure-trove. However, this does not introduce conditions very different from those obtaining in manufacturing, for the manufacturing industry may find a treasure in a new invention. The essential differences between the exploitation of natural resources and the utilization of them is that the primary exploiters are subject to the vicissitudes of exhaustion and the stress of competition may lead them to skim the cream and let the rest go to waste, while the effect of excessive competition in manufacturing is just the opposite, *i.e.*, it is inspirational toward the avoidance of waste. As mining and lumbering concentrate in the hands of great companies, the raw materials becoming the foundation of an integrated business, they tend to be operated according to manufacturing principles rather than on those of the adventurer.

### Soundness of Metal-mining Industry

I think that on the whole we kept our metal mining industry upon a fairly sound basis up to the advent of the war, since when it has been the victim of unfortunate circumstances, rather than its own folly. Although of immense importance, it is conducted by a small personnel, only about 150,000 men being engaged, which is the result of the mechanicalization that our engineers have accomplished. In general, the personnel obtains full-time employment. There is overdevelopment, to be sure, but the adverse consequences of this, as well as those of ups and downs in the market, fall more upon the stockholders than they do upon the workers. I have in mind especially the copper, lead and iron industries. The situation in zinc has never been so good as in the other branches. Following the war, however, we have had new and unfavorable conditions in all of the branches of metal mining, and how we are going to conform to them we do not yet know.

We must not, however, seek to excuse ourselves, but rather should we consider that our industry plays a part in the entire economic fabric of the country and that as a whole we are not attaining the efficiency that is possible. The fundamentals are to be looked for, not in our methods of doing our work, although that is a subject of great importance, but rather in the economic conditions that attach to an industry more workers than is needful and in those that produce severe undulations in the scale of employment even among those industries that are not overmanned. The underlying cause may be summed up in the single word "miscalculations." If I were less practical and more theoretical I might find myself arguing toward state socialism, which I abhor in common with all other varieties of socialism, but my philosophy, together with my observation of experiences, teaches me that that is wholly wrong. Miscalculations are manifestly due to ignorance. Where then are we to seek the remedy? Not among politicians, for we have learned too well that in industry the hand of the government is the touch of death. Not in labor, for labor does not know enough, and the most we ask of it is not to be an impediment. Not among capitalists, purely speaking, for they are inert and about as helpless as labor. There remains only management, whereof we engineers constitute a part. It is management that must shoulder the whole responsibility. There is no use in debating any assessments of blame between management and labor. Let us forget the word blame and assume the whole of the responsibility. This will be looking forward, not backward.

What, then, does this mean and imply? The answer is simply what is expressed in this formula:

*Miscalculations in industry will decrease along with increase in the transparency in industry, which tends toward the establishment of equilibrium.*

Transparency in industry means merely the acquisition of knowledge about it and thereby the ability to see through it and ahead. The basic cause of booms, with all their evils of price inflation, over-expansion, waste and inefficiency is that we fail to look ahead. In times of depression we should prepare for the future, and by doing so we can cure the depression itself. It is largely absence of knowledge of conditions, and the obscuration of our vision, that prevents us from doing this. It is vitally necessary to the industries of the country to have illuminating statistics of production and consumption, producing capacity, and all other factors, and to have such statistics promptly available. The position of the business man who does not have all the needful facts is like that of the automobilist who undertakes to drive without headlights.

The formula that I have offered does not hold out any promise for an early, complete solution of economic troubles. I think it will be about the millenium when that result is achieved. But we can progress. Indeed we are doing that now. Yet it is going to be a long time before much can be accomplished, simply for the reason that our existing knowledge is so scanty and imperfect. In adding to knowledge we, as engineers, are playing our part. The introduction of this subject into our discussions is an inspiration to us to speed up. Just as in the war, when we learned how to coöperate better, there is still a call for everybody to do his bit. Let illumination and clear-thinking be our mottoes.

# The Engineer and the Federated

AT THE dinner at the Cosmos Club in Washington, tendered to Herbert Hoover on Jan. 5, on the occasion of his retirement from the presidency of the Federated American Engineering Societies, he made an informal speech in which he pointed out not only the unique position which the engineer now occupies by virtue of the new Federated Societies but also the opportunity that is thus presented for national service. In this connection and in pointing out some of the reasons for the present economic maladjustment, Mr. Hoover said in part:

This body has entered upon a path of public service that is unique in the whole United States.

The engineer has devoted himself all these years to the upbuilding of the material values of the United States. He has done that effectively—more effectively than has been accomplished in any other of the great countries of the world.

The birth of this society marks the evolution of the engineer into an interest in public affairs. With his intelligence, his experience and training and the unique knowledge that he possesses not only of the material but the intangible values among our people, he is now organized so that his united voice may become heard outside of his profession.

We have probably 175,000 engineers in our country, representing an intellectual possibility for service possessed by no other group. It is therefore an augury of real social development when the engineers of the United States join together for purposes of public service.

This association has the unique value among the associations that it can not have any material interest for its purpose. No engineer can receive any material benefit from it. It can advance no economic interest. It can not therefore be charged with any ulterior motive.

We resolved early in the progress of the Council to undertake an investigation into the elimination of waste—a problem with which the engineer alone was fitted to deal, a problem that had not come in for solution outside of engineering circles. As a result of the investigation carried on during the past year and of the report made, there has been an enormous expansion of the consideration of these fundamental questions—questions that enter into the whole problem of the standard of living of our people.

We have enlarged our vision as to what constitutes waste. We are suffering today from one of the most fearful wastes that can come to us in that we have from two to three millions of idle men.

There are many ramifications of the waste problem which you are familiar with, many, more familiar than I am, but there is one factor in the saving of waste that I believe the engineers might give further consideration to and perhaps more investigation; and that is the problem of a larger view in electrification.

We are all aware of the results obtained in the investigation of the superpower development of the Atlantic seaboard. Superpower is not impossible in many other sections of the country. We are indeed on the threshold of enlarging the distances of transmission. We have the possibility of reducing waste through a large phase of electrical development made during the past thirty years. The American people have no appreciation of the possible results and the added efficiency, productivity, safety and advance that could be obtained in the enlargement of our entire electrical equipment. And there is no body that could give this problem such consideration and so illuminate it in the national sense as this Council could do. Indeed, it requires the services of every branch of engineers that compose the Council. With the possibility ahead of us of the development of some twelve to fifteen millions of horsepower, the consolidation of hundreds, even thousands of minor plants, the enormous savings to be made through the substitution of electrical power for steam—there is a probability of the greatest material saving of waste possible in any country in front of the American people.

It is one thing to suggest a problem and another thing to suggest its solution. It is a far more difficult thing to state a problem in a fashion that people will understand and state its solution in a fashion that will carry conviction. An association of this kind has the opportunity to develop popular conception of its ideas more effectively than any other group in the country.

There is no state or city or municipal government that does not need the advice of the Engineering Council. There is no problem either in federal or state or municipal legislation that does not at some point touch upon material construction and therefore come within the purview of the engineer; so that while the Council, in Washington and in those centers where the directors can keep in contact with needs and the problems in hand, does great service, the same opportunity and the same need exist throughout the country.

I know of no way of inspiring service except by contact. That service, the country needs. It needs the plans and the intelligence of its engineers—the men who have, in the very nature of their work, the inspiration and enthusiasm and yet are great realists in the work—and they are the men who should be heard from.

# Elimination of Waste in the Coal Industry*

BY EDWIN LUDLOW

Past President, American Institute of Mining & Metallurgical Engineers

IN CONSIDERING the waste in the coal industry, which is the title of this discussion, we must entirely eliminate the anthracite region. The demand for anthracite has been constantly increasing and the mines have been able to run during this last year, while the bituminous field was idle for two-thirds of the time. It is on a 100 per cent. basis, which is the best answer to any waste in industry investigations. The anthracite region is also in a very much better position on account of its control by very large companies which realize that their resources are limited; they must husband these resources in every way and they are making the most careful study of methods of mining and preparation to avoid any possibility of waste. This is well known and realized by the managers of those companies. Even the fine slush which was formerly thrown away is now being stored in the hope that methods will be found by which it can be used economically, either in briquet or pulverized fuel in coking. This has been tried.

The anthracite factor may be dismissed from the waste in industry discussion, except as it applies to the general public that burns anthracite; there is a tremendous waste of anthracite in the burning of it. Looking at the ash piles where anthracite is burned and seeing the amount of carbon that comes away with the ashes, one realizes that proper efficiency is not obtained in the burning of that coal. Even its higher cost does not seem to bring people to a realization of the necessity of conserving and burning properly the entire coal carbon content of what has cost so large a price. Many people feel that they want to have the coal as large as they can shovel into the furnace; they do not realize that the small coal makes just as many heat units and can be bought at half the price. Consequently, the demand is continually in excess of the probable production for the larger sizes of anthracite, while the smaller sizes, such as large buckwheat and pea, are a drug on the market and can be bought at nearly half the figure; and yet, if properly burned, these produce just as much heat and can be used with a much greater economy than the large egg and stove.

In the bituminous field there is a tremendous waste. The production this year was only 410,000,000 tons, against 550,000,000 last year, and with a potential capacity of 800,000,000 tons. There is a tremendous wastage of development and wastage in the competition that goes on; and there is very little excuse for it. Fortunately, most of the coal operators in the bituminous field are optimists. If they were not, they would never go on or stay in. Almost every summer they are idle a large portion of the time, but when winter comes around they have orders in excess of their production, on account of short car supply. They go on, therefore, into the next spring and develop, hoping that next winter the car supply will be better. It is that optimism that keeps on developing the soft coal field. There is another feature that comes in and that is the belief that a great many companies have that they can go into a virgin field and produce coal cheaper than from old mines which have been running for a good many years and must therefore have pretty heavy maintenance charges. That causes a waste in mining and competitive prices.

## Three Classes of Soft-coal Mines

The soft coal mines should be divided into three classes, according to the methods of mining: First, those that are under the control of large leasing companies that have bought up the land, have leased the properties on royalty and have an efficient corps of engineers not only to watch the operations but to draw up the leases; second, the mines that are owned by large companies and must conserve their resources and obtain as much coal as is possible from their properties —they also are large enough to employ an efficient corps of engineers; third, a class that is to a large extent composed of purveyors of coal or leasers of blocks of land from different owners. They make these leases with the owners, who are not coal men and who have no engineers employed, through lawyers who know nothing about methods of mining or how proper protection is afforded to their clients; and in consequence they are enabled to go into these properties and gouge out the cheapest coal when the market requires. It is cheaper

* Address at joint meeting of Mining and Metallurgical Society of America and American Institute of Mining and Metallurgical Engineers, Feb. 22, 1922.

Digitized by Google

for them to leave a foot and a half of top-coal to hold up the roof than to put in timbers. Mines of that kind are scattered through Illinois.

The subject of waste in coal mining, and what can be done by better methods of mining, was probably better brought out by the paper of Mr. Clagett,[1] who represents the landowners who lease a large part of the coal in the Pocahontas field, than anything yet given before the Institute. He gave the percentages of extraction through periods of years and showed the beginning of a little over 1000 tons a foot-acre brought to an extraction of 1400 tons a foot-acre, and also showed that the percentage of recovery is coming up now very close to the 90 per cent. line, which is about as close as we can work with any method except possibly the longwall, which was not applicable to that field.

The waste in industry in the amount of coal that is being left in the mines and there abandoned is really becoming an important feature in the economic life of our country. Formerly we lived on the theory that we have "coal to burn," but now we are beginning to realize that the best of our coal is becoming a little scarcer and that greater care should be exercised. The engineers are the ones to take up this matter, and the papers that we have had read before the Institute on existing conditions of mining are very illuminating. The publication of those papers and the diagrams of the methods by which the largest extraction was obtained should be of the greatest value to mining men all over the country.

### Model Lease Needed

There is one thing more that should be done for the protection of the coal industry, and that is that men like Mr. Clagett, who have been making leases, should draw up a model form of a lease that would be so advertised that the lawyers who draw up these leases for their clients would know about it and would use it for the protection of their own clients.

The developments that have been going on and the large excess of capital invested in coal mines is due to the very cycles of excessive demand for coal such as we had in 1920, when, owing to the switchmen's outlaw strike, there was a shortage of transportation which prevented coal from getting to the consumer. The market got excited and became a buyers' market, where men rushed in and bought at any price; others who heard of coal lands rushed out and leased them and the consequence was the development of 200 new mines in that year which had no market for coal as soon as things were restored and transportation became normal.

The method of handling was hardly determined. It was a question of transportation, not of industry. The outlaw strike shortened the car supply so that the coal could not be moved on contract, which had a most demoralizing effect. It produced an excessive amount of coal development and this has had a most clogging effect on the market in every part of the country.

The great trouble with the coal business, also, is the short-term contracts. Every man who loses a contract this year knows that that contract runs only for a year and he keeps up his organization and sharpens his knife in order to take a whack at the same contract next year and get it back. If contracts could be arranged on a longer-term basis, it would give much more stability to the coal operations. Investors in coal would feel that they could go ahead with development under the security of a certain market at all times of the year. Prices, of course, would fluctuate, but they would then have something to go on; there would not be the same ambition to develop any little piece of coal available. It would have a strong, stimulating effect, and it would have what the industry must have—a survival of the fittest. We have more mines than we need in this country; we must get along with fewer mines and keep them running more steadily. It is the only solution of that particular waste in industry. It will save a waste in labor, in capital and it will economize in every way and save a great deal of the waste in mining; mines cannot be kept in proper condition when they are running only 30 per cent. of the time.

There is another waste in mining in the bituminous field, in which I hope the public will help; that is in the burning. Some reports made on that subject showed that the best public utility in Massachusetts reduced its coal consumption 20 per cent. on the average. If a large public utility purchasing 500,000 tons a year could make a 20 per cent. saving, a great deal of money might be invested in better boiler practice. The boiler practice all over this country is extremely bad. It is being developed gradually by large public utilities and their results are continually improving; but if we could only get the burning of the coal even to the average of the public utility, it would represent a tremendous saving in the amount of coal consumed each year—a saving that would be a saving in wealth to the country, because we cannot continue to exhaust our coal resources at the rate we are now doing and expect to keep it up forever.

This matter is a question that the engineers need to take hold of. This investigation should be made by mining men, by coal men, and the only way to obtain results from it is to show what should be done, both in mining and in burning coal, so that a man can see for himself whether his own plant is up to the standard or not.

The whole subject must be one of continuous study. It must be studied, though, by men trained in the business, and it should be taken up by a committee of the Institute and not be left in the hands of men who are not in the coal business; efficiency engineers may be very good in their own way, but they do not know much about underground work.

# Engineer's Relation to Elimination of Waste in Mining*

By J. PARKE CHANNING

Consulting Engineer, New York City

ALTHOUGH the original thought of investigating waste in industry came from a mining engineer, Herbert Hoover, and although the chairman of that committee was a mining engineer (although the real work was done by the vice-chairman, L. W. Wallace), it is an interesting commentary that when the report first saw light, at St. Louis, on the first of June, 1921, some people most violently went up in the air when it was submitted by the representatives of the mining engineers.

At the time they resented most markedly the report of the committee that 50 per cent. of the waste in industry, or as Mr. Ingalls in his paper has properly said, inefficiency in industry, was to be laid upon management. The reason for that seems to have been that, as a whole, the mining industry is pretty well organized and is superior to a large number of manufacturing industries including those studied by the Report.

However, this very meeting shows that even the mining engineers have finally realized that there is waste or inefficiency in mining and that a large proportion of it can, with propriety, be assessed against management.

## Ideas Have Been Clarified

After long sessions in determining a name for this Committee, it finally was decided to use the words, "waste in industry." We realized that the word "waste" was probably not the best word, but we realized that it was a striking word and that it was one which would call attention. "Efficiency," and "inefficiency" have been worked to death; the word "waste" had not been used. Of course, the trouble is that a great many people have imagined, with propriety, that when we used the word "waste" it meant waste of material. What we really wanted to bring out was waste from the human side; waste of human effort, both physical and mental.

The Committee has done good work in clarifying our ideas upon this subject. I think that probably one of the very best things was the division of waste and of those four causes of waste, to which Mr. Yeatman called your attention—that is, low production, interrupted production, restricted production and loss of production. Having those four major divisions before us, we know how to properly classify various kinds of waste, and when we know the real causes of things, we know very much better how to take them up and how to correct them.

## Establish Standards of Production

One of the important things, to my mind, in the elimination of waste of low production, in mining, which is mentioned so often in the various industries investigated, is what are called standards of production.

They say, for example, that one of the great deficiencies in the garment trade was want of standard of production; whereas in the metal industry there are certain standards of production.

It seems to me that possibly we could, with great propriety, establish standards of production. It is found that when we get proper standards of production and have them thoroughly understood, we can get along in an industry or in a factory and get good results, whether the men are paid by the day or whether they are paid on contract. It may be possible that in a particular mine this cannot be applied. I think it is possible that we may say, "standard of production for a drift; standard of production for a raise; standard of production for a stope." In other words, so many feet of drill, so many feet of advance, as a proper and a fair day's work; if a man accomplishes that—if on day's pay—he is to be continued; if he does not come up to that, the only thing is to get rid of him. If you are working on a contract basis you know your standard of production, and the man is paid according to his efficiency or what he produces; so that I think that one thing, the standard of production, is the thing that we should look into.

Mr. Yeatman's paper is such a classic that it has covered almost everything which by any possibility I could say upon the subject. The author has touched upon all the points which in my experience I have run across—the troubles that come from the president, the directors, the manager, the staff and the workmen.

* Address at joint meeting of Mining and Metallurgical Society of America and American Institute of Mining and Metallurgical Engineers, Feb. 22, 1922.

Digitized by Google

He has also stressed the one particular thing which I think is most important in the character of attainment of a mine manager and that is, first and primarily, he must be an engineer. He must be a man with technical training, which, perhaps, he may not have acquired in a college, but may have acquired by burning the midnight oil. He must have engineering knowledge so that when his subordinates talk to him, he can answer them in their own language.

It is impossible, to my mind, for a man to come up and be a successful mining engineer through the office, through the business department, through the traffic department. He may come up through the engineering forces, he may come through the assay office, be he not a college graduate, but unless he does have scientific training, scientific point of view, he cannot be a successful mine manager. He must, of course, have business ability. The best scientific mind in the world, without business knowledge, will not make a successful manager. He must, in addition, have knowledge of what we now call human engineering. He must have knowledge of men. He must know how to handle them. He must have the feeling that inspires confidence, not only in the members of his staff, but in the most subordinate man.

Milton H. Smith, a railroad president in the South who died a few years ago, was president of the Louisville & Nashville, and his great success was his great knowledge of men and his love of men. They say that there was not a section foreman that did not know old Milton H. Smith and would do everything in the world for him. First you want scientific spirit and knowledge, business ability and finally knowledge of human nature.

I have just finished reading a most interesting book by Sir Ian Hamilton on the Body and Soul of an Army, and all through that ran his suggestions which in nearly every case apply to the operation and organization of a mine and its reduction and smelting work. One of the things that impressed me more than anything else was that a man in the very highest executive position should not have under him too many men—brain workers like himself, who reported to him and who came to him with the final decision.

His opinion was that no leader of men should have under him a staff of more than six—that when a man attempted to guide more than six men, he either fell down or he killed himself by overwork. He even went so far as to say that he thought that in the very highest position, with the largest responsibilities, possibly three were enough; that as you went down the scale you could have more and more; that a superintendent might have ten men under him, whose minds he had to direct and of course when you got down to a foreman, sub-foreman, the number could be increased.

In my early experience on Lake Superior, the manager of the mine was a Cornishman who had brought himself up to a high standard and who ran his mine always on day labor; his rule was that he had a boss for every ten men and in all my experience I never saw a more efficient or better operated mine.

Mr. Ingalls has also brought out a great deal that is fundamental. We must realize that in mining, as in a great many other industries, a great deal of the fault of waste (I do not say blame—we were particular in our report to eliminate blame) is due to the people still higher up than the managers—and those are the financiers. The financiers, without the proper knowledge of economics, are the people who have caused us either willingly or unwillingly to overequip our industries, not only mining but others. Those are the people who have to be educated and I think the function of the engineer is, as Mr. Ingalls has brought out, to educate the capitalists and to educate the workmen.

I believe that the higher leaders in labor-union circles are students of economics. The newly-created Bureau of Economic Research has on its board members of the labor unions. The recently organized Personnel Research Federation has on it members of the American Federation of Labor. Those men are not socialists; they are not communists; they are not anarchists, not Bolshevists; they are every one of them strong supporters of the capitalistic system of production and they realize just as well as we do that what we want is light and that clarity in industry which for so long we have not had.

## Coming Meetings of Societies

| Organization | Place | Date |
|---|---|---|
| Taylor Society | Philadelphia, Pa. | Mch. 16–18 |

**Experiments on Possible Production from Oil Wells after First Abandonment.**—According to the Chief Petroleum Technologist, the failure to effect greater recovery is due to the exhaustion of the subterranean gas flow. By experimental processes he has shown that it is possible to recover from 15 to 25 per cent. more oil, depending on the pressure used.

# Present-day Iron Blast-furnace Practice

By RALPH H. SWEETSER

Assistant to Vice-president, American Rolling Mill Co., Columbus, Ohio.

THE present state of iron blast-furnace practice is metallurgical rather than mechanical; the tendency is toward intensity rather than toward extension. The engineers have built blast furnaces big enough and strong enough, and have furnished accessory equipment ample and accurate enough for the present state of the art, but the metallurgical side has been too much neglected; the metallurgist, rather than the engineer, is now the man on whom the present and future progress in iron blast-furnace practice depends. The mining engineer has produced great tonnages of iron ores, and has kept ahead of the demands for quantity; now the metallurgist is improving the chemical and physical qualities of this product by ore-dressing and other forms of beneficiation. For a generation or more, the principles of mechanics have had most influence in the advancement of iron blast-furnace practice; attention now is given more to the principles of metallurgy, chemistry, and ore-dressing.

This metallurgical progress is taking place inside and outside the blast furnace. The two great determining factors of the inside operation are the slag, and the rate of combustibility of the coke. Outside the furnace, the progress is, and will be, along the lines of more careful mixing of ores and iron-bearing materials, in the sizing and washing of limestone, and in the character and structure of byproduct coke.

## Blast-furnace Slags

There have been almost as many theories on blast-furnace slags as there have been blast-furnace superintendents; and many of the theories were wrong, including my own.

During the war several important articles on blast-furnace slag were published, perhaps the most notable paper being the one by Alexander L. Feild and P. H. Royster.[1] This article did not at the time receive the attention and discussion it deserved. Blast-furnace men for the most part were concerned in keeping their plants in operation so as to produce the greatest possible tonnage, and there was practically no time for technical discussion. The paper, however, was of the utmost importance and brought out some facts contrary to the general opinion of blast-furnace superintendents. These facts are now receiving more attention and the information developed, and since proved, is being used in burdening the furnaces. Mr. Feild and those discussing his paper pointed to the fact that the information obtained by the use of pyrometers in determining the melting points of slag had helped to remove "another element of uncertainty from the problems encountered in practice." On the other hand, this same paper had some imaginings that did not sound at all practical, though it might be hard to disprove them.

Investigations are being carried on to determine the value of certain slags with special reference to the effect on the blast pressure and the general working of the furnace. The development of the investigations of the Bureau of Mines and of individual blast-furnace men have upset many of the preconceived notions regarding the causes of blast pressure inside the furnace. Further investigations are necessary to demonstrate fully the relation between the composition of the blast-furnace slag and " the sticking and slipping" of furnaces.

## Slag Disposal

The demand for crushed slag as an aggregate in concrete work has increased in recent years, and much blast-furnace slag now goes to the crushing and screening plants. Dry pits and steam shovels are generally used. Where granulating pits are still in use, it is usual to throw the wet slag into piles in freezing weather so as to drain off as much water as possible before loading it into railroad cars.

## Fluxes

More attention is now being given to the question of blast-furnace fluxes than was formerly considered necessary. As a rule, the limestone for blast-furnace flux was chosen on the basis of cost and freight rather than quality, providing the carbonates of lime and magnesium made up about 95 per cent. of the stone. Open-hearth slag is being more commonly used, especially where the blast furnace is a part of the steel plant. This is an economical way to dispose of the slag from the open hearth, and it is a double source of metal and flux for the blast furnace. In some cases the amount used is 10 per cent. of the total ore burden.

Magnesia is still a subject of controversy, but Mr. Feild's statement[2] that "Magnesia (MgO), as such, does not affect the slag viscosity so far as practical

[1] Slag Viscosity Tables for Blast-furnace Work. Abstract in *Trans.* (1918) **58**, 650. Complete paper published by Bureau of Mines as *Tech. Paper* 187.

[2] *Op. cit.*

Digitized by Google

purposes are concerned unless present in amounts greater than 8 per cent.," is being more generally believed.

The size of the flux stone still varies greatly in the different iron-making districts, and in many cases the run of the quarry crusher is accepted providing the fine dust is screened out. It is generally conceded that a closer sizing of the flux stone is beneficial; and where "ballast size" stone has been used there has been some improvement in the working of the furnace. At a few large quarries the stone is washed after crushing.

### Coke

"Poor coke" has been the excuse of many a blast-furnace superintendent for the poor work of his furnace, and no doubt the poor coke deserved much of the blame; but, what is poor coke? The Coke Comittee (Committee D–6) of the American Society for Testing Materials is even sending out questionnaires asking "What is coke?" Some of the poorest looking coke, judging by the old standards of luster, "long fingers," and "metallic ring," now gives the best results in the blast furnace.

Exact specifications for a good blast-furnace coke have not yet been generally accepted, but efforts are being made to find standard tests for determining the value of byproduct cokes. The rate of combustibility has been brought forward by Herman Brassert and others as one of the determining factors of the value of a coke. Resistance to breakage is another quality that is desirable, for which a proper comparative test is being sought. Much valuable work in this direction is being carried on by J. C. Barrett, at the Ohio works, in his tumbling-barrel tests.

It is claimed that if the blast-furnace men can specify a certain rate of combustibility, and a certain toughness of structure, it will be possible for the byproduct coke-oven man to produce the desired coke by carefully mixing the coals for the ovens.

There is need for much research work to determine the proper structure and size of cokes, and to find the right descriptive terms for the relative values of the different cokes.

### Standardization

The indictment brought against "the management" in general, in reference to the responsibility for the excessive waste in industry, has been well deserved by the management of most blast furnaces. Until recently there was not even an approximate rule for determining the tonnage that should be produced by a blast furnace of a given size. In many cases the coke per ton of pig iron at one furnace was compared with the coke per ton of iron at other furnaces without any reference to the quality of the cokes used or to their contents of fixed carbon.

The rule for rating the capacities of blast furnaces adopted by the Southern Ohio Pig Iron and Coke Assn. (published in the trade journals) is based on the burning of a certain amount of a "base" coke in a given time (60 lb. coke per cu. ft. of working volume in 24 hr.). Starting with the idea that there is a definite rate of combustibility for a standard coke, assuming that the ore mixture contains 51.50 per cent. iron in the natural state, and arbitrarily using 1800 lb. of coke per ton of basic pig iron when the fixed carbon in the coke is 90 per cent., it is a simple process to determine what any blast furnace should make under varying conditions of coke, ore mixture, and percentage of silicon in the pig iron.

The general acceptance of a standard coke is the next step in the advancement of blast-furnace practice. The United States Bureau of Mines, the American Society for Testing Materials, and other associations are trying to solve this problem.

In the operation of blast furnaces, especially at plants that began when all the pig iron was handled by man power and all the raw material was hauled in buggies, there has been too great a delay in getting rid of old customs and wasteful practices. Many of us can remember when blast furnaces 85 ft. high would have cover plates over the whole length of the casting trough at casting time. Even after the adoption of tap-hole guns, and electric drills for the iron notch, and casting machines in place of pig beds, there was a tendency to retain men in the cast house in greater numbers than needed. This was because there was no accepted standard for a day's work around the blast furnace. The adoption of these standards may seem to work hardships, especially in times of unemployment, but it is the only course to take if management is to get rid of the stigma of wasteful practices.

### Beneficiation of Ores

The physical qualities of iron ores are being improved by all the old methods of washing and roasting brought up to date, such as sizing (and crushing where necessary), washing, drying, nodulizing, sintering, and magnetic concentration. The sintering process has found extensive use in changing flue dust into a desirable blast-furnace raw material; it is also successfully used in preparing fine magnetic concentrates for blast furnace use; in some instances the sintering process is used instead of roasting for the removal of sulfur.

### Cost Accounting

Great progress in blast-furnace practice was made by the adoption of the Croxton Efficiency System with its uniform method of cost accounting. However, this method allowed only a comparison between one month's cost and another, or else only between the cost at one furnace and the cost at another. The only true comparison is between the actual cost for a given month and the standard cost for that month at that particular furnace. Such a comparative cost system has already been put into use.

Digitized by Google

The pig-iron cost sheet at most blast-furnace plants has been used almost exclusively as a guide for the sales department, and it has seldom been used in its other and more important function, as a guide for the successful operation of the blast furnace itself. Such a cost sheet, in order to be of full value to the furnace superintendent, must be promptly available and approximately accurate. When the actual amounts of ore, coke, limestone, labor and supplies, and the actual costs per ton of pig iron for these items, are compared with the ideal costs for that month, using standard amounts of materials and labor at the actual prices and wages, then, and then only, is a comparison made that is fair to the management, to the superintendent, and to the furnace.

In spite of the increased cost for freight in assembling raw materials for making pig, the location for new furnaces seems to be governed more by the market for the ron than by the location of any of the raw materials.

## "Synthetic Gold"

PROFESSOR Irving Fisher, of Yale University, is the present-day leading exponent of the quantitative theory of money. According to this theory the prices for commodities are a direct function of the quantity of gold existing and available as a medium of exchange. Professor Fisher has proposed to abolish the fluctuations that he attributes to this cause by a plan for "stabilizing the dollar," which dispenses with gold. There is, of course, no doubt that the influx of a new, adventitious supply of gold would have a profound effect upon prices, just as did the bringing of the treasures of Mexico and South America to Europe by the Spaniards in the 16th century, but the quantitative theory, which has been controversial for 300 years or more, has never been universally accepted, and the economic events of the Great War did more to discredit it than anything else.

However, Professor Fisher is unshaken and he is ever in a state of mind for seeing bogies. Recently at the London School of Economics and Political Science he declared, "on credible authority," that a German chemist had discovered how to make synthetic gold, and suggested that these wicked (and scientific) Germans are going to make the reparations scheme ridiculous by paying off in a metal that will henceforth have only a nominal value. Lest gold miners, who may have seen this declaration widely published through the press, become scared, we give some words of comfort, which we can do no better than in the language of the Scientific Correspondent of the London *Times*, as follows:

> It is dangerous to deny the possibility of any achievement of science, but I do not know of any existing knowledge which suggests that a chemist can yet transmute the baser metals into gold. The transmutation of elements has indeed been accomplished, and theory now points to all the elements being built up of common materials. The radioactive elements disintegrate very slowly but the disintegration is spontaneous, not a result of laboratory methods.
>
> The energy locking the structure of these heavy elements is prodigious and requires prodigious forces to unlock it. Possibly a process will be found, or may have been found, by which the application of radioactive substances to mercury or lead breaks these down, leaving gold as the residue. The stock case of transmutation of an element is that of nitrogen. Rutherford, by bombarding it with alpha particles, succeeded in breaking it up into hydrogen and helium. But even if it were possible, the purchase of radium to transmute lead or mercury into gold would not be an economical process.
>
> It is to be noted that all the cases of transmutation, spontaneous or induced, known as yet are examples of analysis, the breaking up of a more complex element into simpler elements. The triumphs of synthetic chemistry, where simpler substances are combined to produce more complex substances, relate to molecules, not atoms. The forces by which atoms combine in molecules are not only almost infinitely smaller than those which cause the adherence of protons and electrons into the atoms of elements, but are well within the range of experimental handling.
>
> The contrast between molecular and sub-atomic energy may be realized by recalling a famous dictum of Sir Oliver Lodge. He calculated that the energy within the atoms of the piece of chalk which he was using to make a diagram on the blackboard amounted to 300,000,000 foot tons. I do not know if the molecular energy in the same piece of chalk has ever been calculated, but at the most it is in the order of inch-ounces. Could the sub-atomic energy be harnessed it would raise 100,000 tons to a height of 3000 ft.—possibly more than enough to build the pyramid of Cheops. The molecular energy can be harnessed, and I doubt if it is more than that used in laying a trowelful of cement between two of the blocks.

We may amplify this with a few sentences from a lecture at the annual meeting of the National Academy of Sciences in Washington in 1914, by Prof. Sir Ernest Rutherford, the great authority on the constitution of matter and the evolution of the elements. The transformation of matter has indeed been definitely proved. For example, starting with uranium there is derived ionium, then radium, next polonium and finally lead. The primary element of this series is half transformed in 5,000,000,000 years, it is calculated. Half of the ionium changes to radium in 200,000 years. Radium becomes polonium in 2000 and some odd years, while polonium, the sprinter, becomes lead in 136 days. Thorium is known to be a primary element whose radioactive life is even longer than that of uranium.

The processes occurring in radioactive matter are spontaneous and uncontrollable. There is at present no evidence that we shall be able in any way to influence them. This would only be possible on a large scale by altering the rate of radioactive change and causing an element like uranium or thorium to give out its energy in a few hours or days instead of during some billions of years. Radium emanation changes half to radium A in 3.85 days and in that period one pound of the gas emits energy equivalent to that of an engine working at 128,000 hp. per day. This affords some indication of the intensity of the forces required to build up lighter into heavier atoms. Professor Fisher and the gold miners of the world may rest assured that German schemers are not going to play any trick in the matter of reparations by flooding the world with "synthetic" gold.

# A Code of Ethics for Engineers

THE Joint Committee appointed to consider a Code of Ethics for Engineers recommends, after deliberate consideration, that each participating Institute or Society adopt the short simple Code of Ethics following this report.

The Committee further recommends that the following method of interpreting and administering the Code be adopted by each participating Institute or Society after any necessary provisions have been made in the Constitution and By-laws of the Organization.

The President of each Society or Institute shall appoint a *Standing Committee on Professional Conduct*, to administer the Code of Ethics. The duties of such a Committee shall be to interpret the Code and to render opinions on any cases of questionable conduct on the part of members that may be submitted to the Committee. These interpretations shall be reported to the Executive Board of the Institute or Society who may approve these interpretations, or take such other action as may seem just and necessary. The reports of the Committee on Professional Conduct, when approved by the Executive Board, shall be printed in abstract *and in anonymous form* in the Institute's or Society's monthly journal for the instruction and guidance of fellow members.

This Committee on Professional Conduct shall be appointed in each Institute or Society by the President holding office at the time of the adoption of this Code and shall consist of five members, one appointed for five years, one for four years, a third for three years, a fourth for two years and a fifth member for one year only. Thereafter, the President then holding office shall appoint one member annually to serve for five years, and shall also fill any vacancies that may occur for the unexpired term of the member who has withdrawn. These appointments shall be made from among the older members of the Institute or Society, so that advantage may be taken of their mature experience and judgment. The Committee after appointment shall elect its own chairman and secretary. The Committee shall have power to secure evidence or other information in any particular case not only from the organization's own members, but if it should seem desirable, from men in other professions. The Committee may also appoint sub-committees to consider certain cases when deemed necessary.

This Committee shall investigate all complaints submitted to it *by the Secretary of the Institute or Society* bearing upon the professional conduct of any member and after the member, involved has been given a fair opportunity to be heard, the Committee shall report its findings to the Executive Board of the Institute or Society. This report may in some cases suggest certain procedure of the Executive Board.

The Executive Board of the Institute or Society shall have power to act on the recommendation of the Committee on Professional Conduct, either (1) to censure by letter the conduct of the member who has acted contrary to the Code, if the breach is of a minor character, or (2) to cause the member's name to be stricken from the roll of the Institute or Society.

Copies of all reports made by a Committee on Professional Conduct to the Executive Board of each Institute or Society shall be furnished to each other Committee on Professional Conduct administering the Code. This will keep each Committee advised of the interpretations of other Committees, and in time an extended interpretation of the Code can be written based on the reports of the various Committees on Professional Conduct.

As interpretations of the various Committees on Professional Conduct administering this Code may vary at times, it is recommended that the Chairmen of these Committees of the various Institutes or Societies be authorized to act as a Joint Committee to review such differing interpretations and to bring them into unity with one another."

Engineering work has become an increasingly important factor in the progress of civilization and in the welfare of the community. That the dignity of their chosen profession may be maintained, it is the duty of all engineers to conduct themselves according to the principles of the following Code of Ethics:

1. The Engineer will carry on his professional work in a spirit of fairness to employees and contractors, fidelity to clients and employers, loyalty to his country and devotion to high ideals of courtesy and personal honor.
2. He will refrain from associating himself with or allowing the use of his name by an enterprise of questionable character.
3. He will advertise only in a dignified manner being careful to avoid misleading statements.
4. He will regard as confidential any information obtained by him as to the business affairs and technical methods or processes of a client or employer.
5. He will inform a client or employer of any business connections, interests or affiliations which might influence his judgment or impair the disinterested quality of his services.
6. He will refrain from using any improper or questionable methods of soliciting professional work and will decline to pay or to accept commissions for securing such work.
7. He will accept compensation, financial or otherwise, for a particular service, from one source only, except with the full knowledge and consent of all interested parties.
8. He will not use unfair means to win professional advancement or to injure the chances of another engineer to secure and hold employment.
9. He will coöperate in upbuilding the Engineering Profession by exchanging general information and experience with his fellow engineers and students of engineering and also by contributing to work of engineering societies, schools of applied science and the technical press.
10. He will interest himself in the public welfare in behalf of which he will be ready to apply his special knowledge, skill and training for the use and benefit of mankind.

The Joint Committee on Code of Ethics was composed as follows: Representing the A. S. C. E., C. C. Elwell, A. M. Hunt; representing the A. I. M. E., J. Parke Channing, Philip W. Henry; representing the A. S. M. E., A. G. Christie, chairman, H. J. Hinchey, Chas. T. Main, J. V. Martenis, Robert Sibley; representing the A. I. E. E. Comfort A. Adams, G, Faccioli, Geo. F. Sever, L. B. Stillwell; representing the A. S. H. V. E., Frank T. Chapman, S. A. Jellett, Perry West.

# Advantages and Disadvantages of Licensing Engineers*

By B. B. GOTTSBERGER

Consulting Mining Engineer, New York City

I HAVE given considerable thought during the past year to the subject of licensing of engineers and particularly to the position which the mining engineer should take on this question. I have found, however, that it is not a subject which yields much result for the thought expended on it. So far as any published record will show, mining engineers have been either ignorant of the extent to which the movement for the licensing of engineers has progressed or else indifferent to it.

It is true that the Mining and Metallurgical Society of America, by a questionnaire sent out to its membership, did a great deal in calling this matter to the attention of the mining profession, and so far as I know, the report of its committee, which analyzed the replies received, is the only published statement of the feelings and opinions of our branch of the engineering profession. It is to be hoped that the conclusions shown by that report, namely, that mining engineers are almost unanimously opposed to the principle of licensing and consequently any legislation dealing with it, has received serious thought and that we are ready for an even more thorough consideration of the subject.

## Nineteen States Require Licenses

Up to the 26th of July, 1921, laws dealing with the registration of engineers had been passed in 19 states. Four of these did not attempt to cover the entire engineering field but dealt with restricted portions of it, such as structural engineering, civil engineering, and in one state, drainage, highway, state and municipal engineering. The principle, however, is the same, and the idea is certainly rapidly gaining strength, in certain quarters, at least, that the profession of engineering is one that for the protection of the public must be regulated by law.

In general, these laws provide that within a time limit stated in the act, engineers desiring to practice must qualify before boards of registration and obtain certificates showing that they are authorized to practice. The machinery for carrying out these laws consists of boards, variously known as state boards, for the registration, examination, of licensing of professional engineers, architects and land surveyors. After satisfactorily fulfilling the requirements set up by the board, applicants receive certificates of registration and are provided with seals which they are authorized to use on all reports and drawings prepared by them.

As the notice of this meeting which was sent out to the members would indicate, fees are charged for the privilege of registration, varying from $15 to $25 in amount, with the provision that an additional payment must be made upon the annual renewal of the certificate which is in most cases required. This fee is variously placed at from $1 to $10.

## Citizenship Required to Practice Engineering

I will not attempt to set out here any statement of the qualifications demanded by these laws as a preliminary to the issuance of a license, as this is rather an involved matter to summarize and as in the first instance each engineer is concerned most directly with the qualifications called for in his state of residence. I would, however, like to point out that in 11 states United States citizenship is required, on the face of it a most natural qualification, but one somewhat disturbing to the mining engineer when he thinks of the possible necessity of establishing his own qualification to practice in foreign countries. Once having successfully established his right to practice in his state of residence, the engineer is naturally interested to know to what extent his standing will be recognized in other states of our country. On looking into this question he will learn something not entirely pleasing to him. He will find that if legally authorized to practice in his own state he will be welcome for a period not to exceed 30 days in any one year in the states of Arizona, Minnesota, New Jersey, New York, North Carolina, Oregon, Pennsylvania, and West Virginia. The other 11 states will apparently have nothing to do with him until he has first made application for a local license and paid the necessary fee, although a few states, namely, Arizona, Minnesota, North Carolina and West Virginia, grant him the privilege of consultation with local registered engineers. For this so-called reciprocity feature to be operative, it is usually required that the local boards shall from time to time investigate the requirements for registration in other states and if they find that these are not lower than in their own states, the reciprocity clauses will be effective. Here arises the question of the standing of an engineer living in a state

* Address at meeting of New York Local Section, Jan. 11, 1922.

Digitized by Google

where licensing is not required. There is no basis of comparison as to qualifications with those states having license laws although, as he is not forbidden to practice by law, apparently he would be considered qualified. To those doing business in New York state, it is of particular importance to know that the reciprocity clause applies only where a mutual agreement has been entered into by the regents of the University of the State of New York and the boards of examiners of other states, a provision which I understand the board of regents has not taken steps to carry out.

This is a very sketchy outline of the method of operation of registration laws, but of far more importance to my mind than the structure of the law is the question of the scope of its application. It is on this point particularly that thought on my part has yielded very meager results. After having read the definitions set out in those laws which attempt to draw a line around the field of engineering and to say who is and who is not an engineer, I confess myself very much at a loss. If my information is correct, six laws contain so-called definitions of engineering. The other states, as a rule, content themselves by saying "You shall not practice as a professional engineer unless licensed so to do." I find that these definitions can be roughly divided into three sets. I will give an example of each.

Florida, Iowa and Oregon consider the question covered by the following:

A person practices "Professional Engineering" within the meaning of this Act who practices any branch of the profession of engineering other than military engineering. The practice of said profession embraces the design and supervision of the construction of public and private utilities, such as railroads, bridges, highways, roads, canals, harbors, river improvements, lighthouses, wet docks, and other floating property, the design and the supervision of the construction of steam engines, turbines, internal conbustion engines and other mechanical structures, electrical machinery and apparatus, and of works for the development, transmission or application of power, the design and the supervision of mining operations and of processes and apparatus for carrying out such operations, and the design and the supervision of the construction of municipal works, irrigation works, water supply works, sewerage works, drainage works, industrial works, sanitary works, hydraulic works and structural works and other public or private utilities or works which require for their design or the supervision of their construction such experience and technical knowledge as are required in Section 8 of this Act for admission to examination. The execution as a contractor of work designed by a professional engineer or the supervision of the construction of such work as foreman or superintendent for such a contractor shall not be deemed to be the practice of professional engineering within the meaning of this Act, nor shall this Act apply to a person acting as a public officer employed by the state, county or municipality of this state, on work where the estimated cost of the same is $1000 or less.

Here, you will note, the mining engineers are brought within the fold by the words "the design and the supervision of mining operations and of processes and apparatus for carrying out such operations."

New Jersey and Pennsylvania have, to my mind, quite sensibly endeavored to draw up a definition in much more general terms, that for New Jersey being as follows:

Professional engineering as covered by this act means the practice of the professional engineer who through technical knowledge gained by education and experience in one or more branches of that profession initiates, investigates, plans and directs the application of the resources of nature to the use and convenience of man; and who represents himself or herself to be such an engineer, either through the use of the term engineer with or without qualifying adjectives or through the use of some other title implying that he or she is such an engineer.

It should be noted that this definition covers the field so thoroughly that one is apparently forbidden to call himself an engineer either with or without qualifying adjectives until he has been licensed.

Our home state contents itself with a still shorter definition as follows:

A person practices professional engineering within the meaning and intent of this article, except as hereinafter stated, who holds himself out as able to do, or who does, the work that an engineer does in the planning, designing, constructing, inspecting and supervising of engineering work, or appliances involved in public or private projects, or in making investigations for proposed engineering projects.

This at least has the advantage of brevity and it is consoling to be told authoritatively that after all an "engineer is as an engineer does."

After reading these definitions, it is evident that if they are to be taken seriously and at their face value, the intention is to prohibit the practice of any branch of engineering to those who cannot qualify under the laws.

Right here is where I think this subject calls for most careful study. I have no hope that a much more satisfactory definition of engineering would result from this, but I would hope that as engineers study their field and attempt to circumscribe it, or to make their field so broad as to be all-embracing, they will pause and consider whether, after all, they care to reserve this field entirely to themselves, and whether they wish to bar out from the consideration of the vast number of problems included under the term of engineering all who do not measure up to the arbitrary standard that they will finally set up as law.

I often wonder what a careful investigation of the origin of many things today considered commonplace in our industrial life would reveal when the credit for the first inception of the ideas was given to its proper source. I do not think that after this investigation engineers would finally feel justified in claiming all of the credit; and would they not have to acknowledge that today some of their most valuable tools came from those who, under the operation of these acts, would be forbidden even to think? I may as well say that my own most serious objection to licensing laws is not that some one unqualified to practice will be barred out for the benefit of the public, but that some other one, or many such, will be forbidden to develop their ideas because we would disown them as engineers.

Leaving this phase of the matter for the moment, let us assume that the arguments of those in favor of licensing are valid, and that the public stands in need of protection from the incompetent engineer. To what extent will the laws already enforced provide this needed protection? In other words, if the laws as drawn provide the safeguards needed, to what extent are they compulsory? In most cases it will be found

Digitized by Google

that laws are apparently of universal application and that practice of professional engineering by unlicensed engineers is positively forbidden. In five states, however, namely, Arizona, Minnesota, Tennessee, Virginia, and West Virginia, licensing is, to a large extent, optional. It will usually be found that in the first section of the law the object of it is set out, and I quote as follows from that of Arizona:

> Section 1. In order to safeguard the life, health and property, any person practicing or offering to practice as an architect, a professional engineer, a land surveyor or an assayer in this state shall hereafter be required to submit evidence that he is qualified so to practice, and shall be registered as hereinafter provided, and from and after six months after this Act becomes effective, it shall be unlawful for any person to practice or to offer to practice in this state, as an architect, a professional engineer, hereinafter called engineer, a land surveyor or an assayer, except under the provisions of this Act.
>
> Section 2. Nothing in this Act shall be construed as requiring registration by an individual, firm or corporation for the purpose of practicing architecture, engineering, land surveying or assaying on property owned or leased by such individual, firm or corporation, unless the same involves the public safety or health; nor as requiring registration by any person who prior to the time of the passage of this Act was engaged in the practice of architecture, engineering, land surveying or assaying, provided, however, such person shall not represent himself as, or use the title of "Registered Architect," "Registered Professional Engineer," "Registered Land Surveyor," or "Registered Assayer" unless such person is qualified by registration under this Act.

Reading Section 1, it is the evident intention of the legislature of the State of Arizona to see that those committed to its care are guarded from incompetency and absolved from the necessity of using good judgment in the selection of an engineer.

What, therefore, are we to think when, in Section 2, we are told that any person in practice prior to the passage of this act may continue provided he does not use the title "Registered Engineer?" This provision, I am told, is the so-called Grandfather's Clause, based on the theory that the right to continue a gainful occupation cannot be taken away by law. It is evident, therefore, that if this proviso must also be extended to all of the states, there is no hope of reforming the practice of the engineering profession until those now in practice are displaced by the rising generation of qualified engineers. Personally I would not claim this to be a serious defect in the law if its necessity were fully established and I would probably applaud the thoughtfulness of engineers in looking so far ahead in endeavoring to carry out the ideals of their profession.

### Does Licensing Safeguard Public?

Assuming again the necessity of these laws, is the profession of engineering one that will be safeguarded thoroughly by the mere establishment by an applicant of his qualifications based on examination and a short period of experience? Possibly so, if engineers are to be classed as workmen carrying out specific tasks for which the necessary qualifications can be outlined. If, however, the real danger to the public should come, not through a lack of fundamental knowledge on the part of the engineer, but through his inability to use good judgment in the application of this knowledge, then I cannot see that the protection necessary is provided for by registration. Personally, I am so inclined to feel that the engineer should be willing to stand on his own feet and prove by his record that he is entitled to employment, that I find it hard to attempt to submit arguments justifying a demand for licensed legislation. I have so far seen nothing convincing in the way of an argument that demonstrated why the public needed this protection, and strangely enough, this question of the public welfare is the only argument I have found in favor of licensing. I have endeavored to find out what other arguments the advocates of this legislation have advanced.

As most of you probably know, the proponent of licensed legislation has been the American Association of Engineers. For some years past this Association has published an official organ, originally known as the *Monad*, and lately published under the title *The Professional Engineer*. Dating back at least to 1918, this Association has published the views of its members on the question and I have endeavored to learn from a study of it what the arguments in favor of licensing are. I confess I cannot submit at this time a complete digest of all of the views expressed, but I do not think I am unfair in making the following quotations:

> Now what is the object of such legislation? I believe the fundamental idea is, and should be, to protect the public, because if this protection can be afforded other equally desirable things will probably follow.
>
> Will a good license law do this? I think it will greatly improve present conditions, and eventually will be successful, granting that high standards be maintained. It is my opinion that the more recent laws give great promise.
>
> In addition to protecting the public, in what ways will these laws benefit the engineer? These ways occur to me.
>
> 1. By forcibly reminding us of our responsibilities.
> 2. By establishing us before the law as professional men.
> 3. As a result of the first two premises, we shall value our services better, and the services will be recognized as professional ones.
> 4. Eventually we shall have more "real" engineers, because we shall expect more of them.

---

> Previous to its passage, a great many incompetent and ignorant men were calling themselves engineers and were getting work by making extravagant claims and offering to do work below the cost of doing it properly. This sort of malpractice has very largely ceased since the engineers license law became effective, though it has not entirely disappeared and probably never will.
>
> The general standard of the profession has been improved, as naturally was to be expected. For one thing, the law makes it possible to state definitely who is, and who is not, an engineer. As the standards of practice have been improved by exclusion of unworthy men, the public appreciation of the profession has been very naturally increased.
>
> The law licenses a man as a professional engineer without specifying any branch of engineering or limiting the man's practice to any one branch. This makes it legally possible for a man to obtain his license by passing examination as a civil engineer and then under it, to do electrical engineering work, or work in other branches with which he is not familiar.

---

> What reasons are there for licensing? Like the ten commandments, one summarises all. Licensing can be justified by a profession on one ground only; namely, the benefit of the public; the protection of life, health and property. Any other attempted justification places the engineer on the plane of a tradesman advocating a closed shop, and while licensing has results directly beneficial to the professional engineer, these are incidental.

Digitized by Google

These quotations appear to be typical of the few arguments I found in favor of the movement. You will note, however, that they are merely statements and that no actual instances of loss or damage to the public are cited in support of them. It seems to me that the case for and against licensing has been very well set out by the Joint Committee on Licensing of Engineers, which opposed the movement before the Massachusetts legislature and which represented a number of engineering societies and sections of national societies with headquarters in Boston, and I would commend this particularly to your attention. It will be found in the December issue of MINING AND METALLURGY. They have attempted to set out the arguments advanced by those favoring the law and it apparently again simmers down to the protection of life, health and property of the public without, however, much in support of the claim. Turning to their arguments against licensing, I am particularly impressed by the following:

> Prof. George F. Swain pointed out, at the hearing, in the clearest possible way, the character and the extent of the safeguard to the public that exist at the present time relating to the construction of buildings, public and private utilities, etc., through supervision by competent commissions and engineers, through building laws and other special laws requiring official supervision and approval of plans, inspection of work in process and of finished work, and expressed the opinion that if such measures were not sufficient the wise policy would be to add to them and to amend them in such a way as to cure their defects, but that no possible method of registering engineers could take their place or could provide a system of safeguards to society that was comparable with them in effectiveness.

From all this it must be evident to you that I am decidedly opposed to the licensing of engineers. I do feel, however, that if we decide to come out with active organized opposition to it, it will be necessary to consider carefully why the forces favoring this movement have been so successful in accomplishing their object in so many states of the union, and before committing ourselves to active opposition we should assure ourselves that we have ground for successful operations and that we may count on the support of our brother engineers.

---

## Skull in Lead-Zinc Deposit in Rhodesia

WHAT is said to be the most important find in anthropology since the Piltdown skull is a human skull recently discovered during mining operations at the Broken Hill mine in Northern Rhodesia, which may prove to be a new link in the pedigree of mankind. It has been presented, by the mine operators, to the British Museum.

The skull was found 60 ft. below water level, at the foot of a "Bone-Cave," with other human bones, part of which were destroyed by the native laborers in their digging. These were the only human remains out of many hundreds of tons of bones that have been removed during mining operations. "Fossilized and partly fossilized remains of elephants, lion, leopard, rhino and hippo and many more animals and birds have been found, all of which were destined to pass through the smelter to obtain the metals which have replaced the lime of the bone; for chemical examination has shown that the lime has been largely replaced by the phosphate of zinc and lead." Before mining operations commenced, there was on this spot a kopje, or hill, 50 to 60 ft. high. Mining operations have demolished this hill and have excavated to the depth of over 90 ft. below ground level where the hill stood, and it was at this depth that the shull was discovered. The entrance to the Bone-Cave was at ground level. S. J. Speak, mining engineer of London, has given us the following interesting theory of the origin of this cave.

"It occurs on the edge of what was originally a sulfide orebody in dolomite, and there can be little doubt that the cave is a natural result of oxidizing and leaching action. The cave contained much debris, and had undoubtedly been used by cave dwellers as a home which they made no attempt to keep clean. The cave also probably possessed the advantage of access to water. We have now satisfied ourselves that water level was much lower in older times than it is now. The skull was found 60 ft. below present-day water level; at that depth we find it necessary to pump 6,000,000 gal. per day to keep our quarry open. The method of occurrence of the numerous bones is one of our evidences of a raised water level, but by no means the only one. Boreholes show some oxidation at depths of 300 ft. The topography of the district in no way suggests the cause of the raised water level. I have no doubt that the original drainage was by underground channels that have since been choked. There is an escarpment 1000 ft. deep about 30 miles away from the mine."

The skull has aroused a great deal of interest and has been discussed at great length by scientists. The Rhodesian fossil skull does not represent a type of man which is new to anthropologists; every feature of this skull proclaims the ancient African of whom it formed part to have been first cousin to Neanderthal man, that peculiar species of humanity which lived in Europe throughout a certain phase of the Ice Age.

We are indebted to Ross Macartney, the manager of the mine, for this information, through the courtesy of Mr. Speak.

**The Miners' Safety and Health Almanac** for 1922 has been issued by the United States Bureau of Mines, in coöperation with the United States Public Health Service. This book, compiled by R. C. Williams, Passed Assistant Surgeon, U. S. Public Health Service, besides containing the usual fund of information concerning sun, moon, wind and weather, preaches crispily and snappily the doctrine of Safety First. It contains many articles by experts in safety, health and sanitation problems, and is intended for circulation among the million coal and metal miners and quarry workers in the United States. Copies may be obtained from the Bureau of Mines, Washington, D. C.

# Correspondence and Discussion

## Copper at Retail

IN CONNECTION with the present cost of copper articles at retail, I had occasion to buy from a Pittsburgh hardware store some strip copper cut from 3/16-in. sheet. The price came to 33 cents a pound. Brass screws an inch long cost about 2-½ cents each from the same dealer, when bought in small quantities, such as a dozen or two.

These prices are not far from what one had to pay 10 years ago or when copper ingots and wire bars were quoted about as today.

MYRON R. WALKER.

Dormont, Pa., Jan. 20, 1922.

## Northwest Mining Association's Position

MY NAME having been prominently displayed in your article in January MINING AND METALLURGY, concerning mining law revision and the present attitude of the Northwest Mining Association in respect thereto, as expressed in the resolutions and analysis of Nov. 19, 1921, I respectfully offer the following comments for what they are worth.

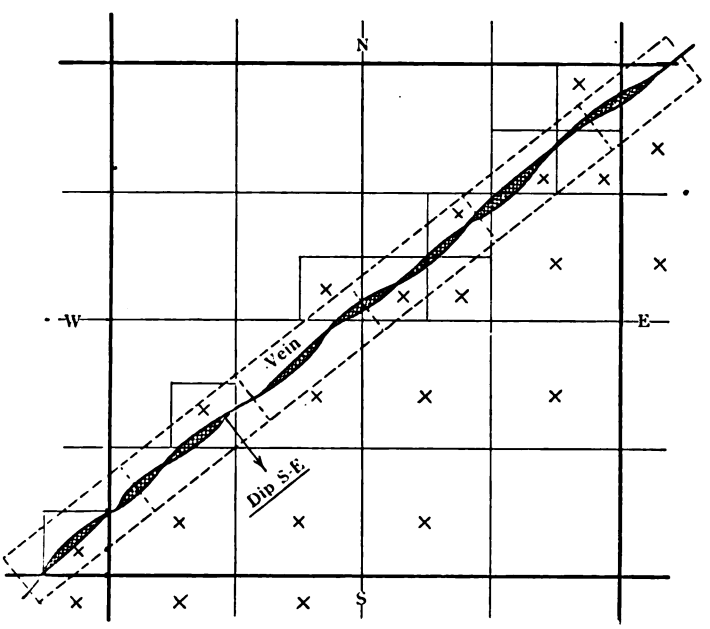
Permit me, first, to note the fact that circumstances often alter cases; also, that there may be a wide difference between a popular demand that something be done, and the opinions aroused by the final form in which it is proposed to do that something.

Again, that there may be a considerable difference between the casual opinions of a convention, which has been requested to endorse resolutions drawn and presented by outside parties, and the opinions of a special committee appointed to pass upon the provisions of a final bill apparently drawn to those resolutions.

Moreover, that there has been an almost complete change of feeling since 1916 in respect to legislation of any sort. All business has been so hampered and harassed by governmental regulations, changed laws and other conditions, that it is loudly crying for a rest, and the mining industry is no exception to the rule.

Finally, that while my name was probably signed to the resolutions of 1916, as president of the association at that time, yet I was not wholly responsible for them; even then I was beginning to doubt the wisdom of changing the extra-lateral right law—a doubt that has since become a conviction, at least as far as the United States is concerned.

Until recent years, I was a strong advocate of an abolishment of this extra-lateral right. Twenty-six years ago I spoke for an hour before a large convention, earnestly urging that immediate measures be taken toward an adoption of the British Columbia mining location; and in the analysis above mentioned, it is specifically implied that if the square location had been



SKETCH ACCOMPANYING RESOLUTIONS OF THE NORTHWEST MINING ASSOCIATION, NOV. 19, 1921.

Showing proposed method of locating mining claims under H. R. 7736, compared with the present system as indicated by the dotted lines. To possess a vein striking as above, and having a flat dip, the tracts marked "x" would be needed under this Bill.

proposed, having one side parallel to the strike of a vein and close thereto, there might have been less objection to the proposal. But to compel locations along the cardinal lines of the public survey would certainly prove impracticable and work much hardship and confusion, particularly on unsurveyed lands. I enclose another sketch in support of this contention.

However, I think that my reasons for a reversal of my former views on this matter are clearly stated in the said analysis and need not be repeated here.

Respecting locations without discovery, much might be said. As you have noted, it was conceded that some *well-guarded* right should be granted where, for instance,

Digitized by Google

geological deductions point to the possibility of mineral although surface signs are absent, or nearly so. Since the bona fide prospector would probably not locate ground in the latter case, he would not be greatly concerned although the speculator might.

No suggestion was made as to *how* this right should be safeguarded because that was not considered to be the province of the analysis, which dealt only with the bill itself. Suggestions were not in order, yet it would seem that it should not be very difficult for competent legal talent to devise provisions that would discourage any but bona fide locators, something that certainly was not done in the present bill.

Regarding subdivision C, section 5, compelling location notices to be filed in the U. S. Land Office *only*, instead of at the county seat, I think that the objections were clearly stated in the analysis. A very important suggestion was made that duplicates of the filings made at the county seat should be also filed in the district land office.

The objection to an acceptance of cash in lieu of actual assessment work is also clearly stated in the analysis, although this may be a matter of opinion as well as of experience.

The mill-site clause was objected to because of the requirement that sites be located on cardinal lines, and not because of the proposed increase in acreage. You will recall that the objection was to the 'method' of location. There is no objection to an increase in acreage, I think.

In conclusion, it seems to me that your wholesale condemnation of the Northwest Mining Association, and myself personally, is unwarranted by the facts. Also, I question your right to challenge the right of any organization, or individual, to a change of opinion in the course of eleven, or even six, years. Much has happened since 1911 and more since 1916.

In reversing itself in the matter of the extra-lateral right, the Association has but answered the question, "What real good would it do, after all, to abolish this right *in the United States at this late day*, when virtually all mineral-bearing districts are already thickly plastered with locations that will hold under the present law? What harm might it work?"

Forty years ago, or even thirty years ago, such a change doubtless would have been a benefit; provided, always, that locations were not required to be made on the lines of the public survey. It would be very questionable today, as a careful study of the situation must show. *Hostility to the apex law has become a habit that has precluded such careful analysis.*

Therefore, I maintain that the present position of the Northwest Mining Association is not only tenable but that it is directly in the interests of the mining industry. Furthermore, its objection has been filed before the bill has passed and the reason has been clearly stated.

FRANK A. ROSS.

Spokane, Jan. 19, 1921.

## Eminent Authority in Favor of Mining Law Revision

YOUR article on the Revision of the Mining Law in the January MINING AND METALLURGY, is admirable. You may be interested to know that about twenty-six years ago, Judge Hawley, one of the most experienced and learned of the federal judges who have had to do with the interpretation of the mining law, expressed himself quite emphatically on the subject. In 1895, in the case of the Consolidated Wyoming Mining Co. v. The Champion Mining Co., 63 Fed. page 549, he expressed himself as follows:

> It would be an Herculean task to endeavor to fathom the complications that are liable to arise in the construction of this statute, and to provide for their solution on any refined method of interpretation. One thing, however, is certain: that unless it can be done, then the statute is radically wrong, and the sooner amendments are made thereto to avoid such difficulties, the better it will be for the mining industry of the country. In fact, it is a question worthy of consideration whether it would not be advisable to have the mining laws amended so as to adopt the Spanish, Mexican and Roman rules and give to the miners a greater width of ground upon the surface, making a square location, and confine the owner of the claim to the ground within the boundary planes of his location in length, width and depth, the same as agricultural land, so as to avoid any further conflict over side and end line propositions that are becoming such fruitful themes of endless dispute and litigation.

When a judge of wide experience refers to such disputes and litigation as endless, it may be taken for granted that he speaks out of fullness of knowledge and it makes one smile to read the assertions of men of no experience in such matters to the effect that all of the questions are settled. Those in possession of the real facts know full well that every decision or interpretation opens the door to other questions and that there are cases now before the courts in which are involved questions which have never yet been decided. In fact, I will cheerfully undertake to present ten or a dozen situations involving extra-lateral rights regarding which no two lawyers of the widest experience in mining will presume to state definitely what verdict would be given by the United States Supreme Court.

In an article entitled "The Relation of the Mining Law of the United States to the Development of its Mineral Resources" published in the *Mineral Industry* in 1894, Doctor Raymond, than whom no one was ever better qualified to speak, expresses his opinion as follows:

> Enough has been written, perhaps, concerning the curious, haphazard origin of our unique mining law and the innumerable disputes which its eccentric, vague, inconsistent and ill-considered provisions entail upon mine-owners—though, perhaps, all these things will need to be reiterated again and again before they will be realized by all parties whose coöperation is necessary to a radical reform.
>
> Enough has been written likewise, perhaps, concerning the object lesson presented at this time by the mining districts of the world, including the greater part of the mining industry of this country, in which mining litigation (in the sense of disputes over the boundaries of mining rights, otherwise held by perfect title) is unknown, while in certain of our States and

Digitized by Google

Territories such litigation burdens the courts, oppresses the owners and operators of mines, and enriches only lawyers and experts. This lesson also may need to be enforced hereafter by repeated exposition; but only because of the slowness of the pupils who should have learned it long ago.

The full development of the mineral resources of the West will never come to pass until the capital it requires is better protected by definiteness in title and boundaries of mining property. And that cannot be done, in my judgment, by any amendment of the present law which shall leave in it the present abnormal, irregular, indefinable, precarious and mischievous "extra-lateral right."

The draft of an amended law was prepared by men who have had years of experience in the application of the present law, who have learned its defects and who have the interest of the mining industry at heart. This does not mean simply one end or portion of the mining industry, such as the prospector, the mine operator, the mining lawyer, the mining engineer or the capitalist. It means the industry as a whole. The criticisms of this bill, which have been voiced from time to time, represent largely one or the other of these special classes. The old-time prospector has largely disappeared and the prospecting of the future will be done mainly by men of large means, better geological knowledge and wider command of all the agencies for discovering ledges and deposits which do not prominently outcrop upon the surface. Most of the easily discovered mines have been found and developed and the annual labor which is performed under the requirements of the present law seldom accomplishes anything of value toward the discovery of new mines.

The locator of a mining claim regards the discovery requirement of the present law as a joke. He boldly sets his discovery monument upon the surface where the wash is 50 ft. deep, tells Uncle Sam that he has discovered mineral in place, stakes his claim and relies upon the generosity and spirit of good-fellowship of his neighbors not to jump his claim or interfere with his possession. The Land Department is assailed if it refuses to patent ground thus fraudulently located and by force of public sentiment or the individual influence of congressmen is coerced into granting patents for land upon which no single bit of valuable mineral in place has ever been discovered. Now, as a matter of fact, the locator is not secure in the possession of the ground which he has thus staked without a discovery and might be ousted by any other prospector who should locate across the territory already staked and first make a discovery. This frequently happens and land is acquired not at $50 per acre *annual rental* but in fee for $5 per acre in large quantities.

The framers of this bill desired to make it possible for the locator of mineral claims upon the public domain to be honest and preserve his self-respect and remain secure in his possession of the ground whereon he desires to prospect before he has made a discovery and to give him ample time to discover mineral. They desired also to make sure that mines are discovered if possible and therefore limited the time within which such land may be held to what seemed to them to be a reasonable period. If five years is not long enough, we are perfectly willing to make it longer but it is seldom indeed that a serious, energetic prospector will desire to hold a piece of ground without the discovery of anything valuable for more than five years. Speculators and men who do nothing to develop the mineral resources of the country are the only ones likely to do so and against them this limitation is directed.

However, you say quite truly that the committee that was asked to give its unremunerated time to the framing of this bill does not intend to engage in any propaganda for its adoption. The movement arose through a general and spontaneous demand for revision along certain definite lines and the bill is framed to meet this demand. If now the criticisms of uninformed individuals, inspired mainly by self-interest, is to prevail upon Congress to reject it, we shall have nothing further to say.

HORACE V. WINCHELL.

Los Angeles, Jan. 11, 1922.

## Licensing a Farce in Colorado

THE licensing law for mining engineers is getting to be more or less of a farce in Colorado. From Sept. 17 to 22, I attended a meeting of the licensing committee of the F. A. E. S. in Chicago to amend the model mining law issued by it, and that meeting afforded both mental and physical perspiration, due to the attempt to define engineering in a hurried heated atmosphere.

We in Colorado are not in sympathy with the general principle of licensing mining engineers. At the close of the 1918–19 session of the legislature, the bill was introduced for the purpose of licensing engineers, by a local branch of the American Association of Engineers, in an underhanded secret manner, without notice to any of the members of the several national engineering societies, and was passed by the legislature. This law was defective in many ways and, at the last session of the legislature, the Engineering Council of Colorado appointed a committee to revise it, and the present law was enacted as the result of such effort.

The so-called "grandfathers" clause permits those practicing engineering to continue to do so without examination, and by so doing, many men wholly unqualified to be called engineers, by the payment of a fee, receive their license, thus lowering to a deplorable extent the standing of those fairly entitled to be so designated.

The local section of the A. I. M. E. discussed the law, and the consensus of opinion was, and still is, that while there might be justification for the licensing of civil, sanitary and construction engineers, there was little, if any, benefit to be had by licensing mining engineers. The development and operation of coal mining has been well and favorably covered by existing laws, as to the safety of life and property, so that there was no need of this law to cover their requirements.

Digitized by Google

The law has not been strictly enforced; if it were, it would adversely affect the mining interests in this state, because the small mine and its development could not afford to employ a licensed engineer, as an intelligent foreman could easily plan the necessary mine development; this I know from actual contact with such conditions; in one case, a man was running an upraise to reach an orebody exposed on an upper level, while in another, the work consisted of running two drifts on ore; there being in the one case, six, and in the other case, eight men employed. There is no question that these foremen were exercising engineering judgment, and as such were subject to the law. Those financing these operations could not afford nor did they need to employ a licensed engineer. In larger enterprises, the companies find it to their best interests to employ a competent engineer, and so far as licensing is concerned, whether or not these company engineers are licensed, is wholly academic.

In conversation, Robert J. Grant, the Examiner of the State Board representing the mining engineers, stated that the examinations he held—and they were very few—were of no real value, the applicant usually being uneducated in an engineering sense. A questionnaire had been prepared by a professor at Golden School of Mines, but it was found too technical for use with the applications. Recourse was thus had to oral examinations, and in view of the number of "grandfather" engineers then practicing, it was hard to refuse the applicant. The wide range of scientific knowledge involved in the various branches of the mining profession rendered it difficult to decide whether or not the candidate was fitted to be licensed. Once given a certificate as a licensed engineer, there was no field of engineering in which he might not engage, be it civil, electric, sanitary, construction, irrigating or mining; hence the safety of life and property expected through the enactment of the law was jeopardized. Mr. Grant is wholly against the principle of licensing mining engineers, for the reason that no good is obtained thereby and it only results in another useless law added to many others found impractical.

There are over eight hundred licensed men in this state, the fees from whom, the first year, amounted to over $12,000. The cost of the State Examining Board was only a few hundred; this year the income to the state is over $4000, with expenses about the same. This money is taken from professional men who have, at least in this state, suffered greatly from lack of employment, and who have in no way benefited by the payment made. If the surplus funds from the Licensing Board were applicable to some purpose useful to engineers, the feeling in the profession might be more kindly disposed towards the law, but the money goes to the general fund and is of no service to them. Here, we could well use it in maintaining a scientific library by the purchase of books and employing a librarian, or it could be usefully employed in aiding scientific research on the complex ores of the state, the oil shales, or developing some use for the rarer metals resulting from smelting operations; as, for instance, there are over a thousand pounds of thallium in the yard of a local smelter, for which there is no sale. Scientific research and investigation of the possible uses of this metal might result in knowledge of great scientific value.

I trust that the foregoing statement is sufficiently clear to give you a fair understanding of the Colorado situation. RICHARD A. PARKER.

Denver, Dec. 23, 1921.

## Licensing Advocates on the Wrong Foot

WRITING as a former member of the A.A.E., I will say that I am absolutely out of sympathy with the efforts of this organization to secure license legislation. That I am not alone in this attitude, I know, from conversations with other members last summer.

Mr. Ingalls has summarized many of the objections to such legislation so ably, in MINING AND METALLURGY for February, that little more can be said from the point of view of the general public.

I do not wish to be understood as minimizing the economic disabilities of the average subordinate engineer, but I fail to see how licensing is going to ameliorate these conditions in the least.

The A.A.E. has simply gone off "on the wrong foot" in this matter, and there is a strong possibility that, in chasing this phantom, sight may be lost of the possibilities for real service through the employment bureaus, and through classification boards in those most notoriously underpaid lines of engineering effort, railways, state and municipal employ.

Lest my statement that I was "formerly" a member of the A.A.E. should convey any false impression, I wish to say that I resigned this year, feeling that in my present rather isolated location, the employment and other services of the A.A.E. could be of very little use to me; and not from any dissatisfaction with the conduct of the affairs of the Association.

HARLAND M. KERSCHNER.

Timmins, Ont., Feb. 19, 1922.

## February Mining and Metallurgy

OWING to some unexplained inadvertence in the bindery, some of the numbers of the February MINING AND METALLURGY have signatures of 16 pages misplaced, which brings some of the advertising section into the middle of the magazine and some of the editorial section among the advertising pages. Perfect copies of the magazine will be sent to all who receive these imperfect copies and who will notify us. This explanation is offered to anticipate any criticism that might arise from a first-impression misapprehension.

# Abstracts of Institute Papers

The following papers were presented at the New York Meeting, Feb. 20–23, 1922. They will be printed in full in the TRANSACTIONS.
A copy of any of these papers complete will be sent free to members on application, for which a request blank is furnished on page 22 of the Advertising Section. Discussion of papers is invited.

## Future Demands on the Oil Industry of the United States

BY JOSEPH E. POGUE, NEW YORK, N. Y.

IN 1920, 531 million barrels of crude petroleum were consumed in the United States. As imposing as this figure is, the fact that the domestic consumption of crude petroleum has increased at an average rate of 10 per cent. a year for the past decade is more striking. Will this rate of increase in demand continue? If so, the year 1930 will call for 1260 million barrels of petroleum—a staggering volume. On the other hand, may we expect the demand for petroleum to grow as rapidly as it did when the automotive industry was having its most phenomenal expansion? If not, to what extent will the growth of oil requirements decrease? When and to what degree will the petroleum industry become affected by the economic law of diminishing returns? Obviously, this matter requires careful analysis, especially as both national and industrial planning must be predicated upon present estimates of the requirements of the future. The purpose of this paper, accordingly, is to project, as closely as present limitations of knowledge permit, the course of the demand for petroleum in the United States over the next 10 years.

Fortunately, there are several scientific methods of approaching the problem, centering around a study of rates of industrial growth, which lend considerable hope that the requirements of the immediate future in this field may be approximated with sufficient closeness to have practical value as a basis of action.

The demand for crude petroleum is the result of the demands for the products made jointly from this substance—gasoline, kerosene, gas and fuel oil, and lubricating oils. The demands for these have grown at different rates, as shown in Fig. 1, which depicts the domestic consumption of the four major products for all years for which there is a statistical record. On this chart, the slopes of the curves are proportional to the rates of growth, and the demand for crude petroleum is thus analyzed into its component parts. Gasoline has become the leading product, setting the pace for the quantity of crude petroleum needed.

Having observed the degree to which the domestic consumption of gasoline is outdistancing the other petroleum products in point of growth, we may examine the relationship that obtains between gasoline and crude petroleum, keeping clearly in mind that we are concerned with relative rates of growth, not absolute magnitudes. For this purpose, it is desirable to separate the supply of crude petroleum into domestic production and imports, and to plot against these factors the domestic production of gasoline. The growths of these three important items are compared, in Fig. 2 (not shown), and to facilitate comparison the figures representing domestic production of crude petroleum are divided by 5 before plotting. This not only lowers the curve (without affecting its slope) to a convenient position on the chart, but it makes it possible for the curve

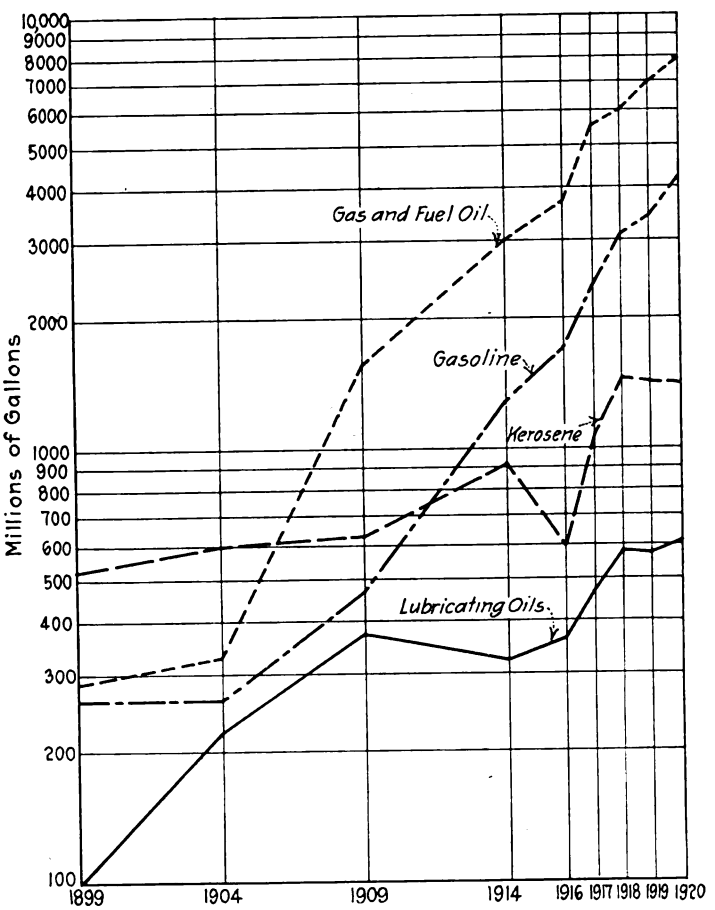

FIG. 1.—RELATIVE RATES OF GROWTH OF DOMESTIC CONSUMPTION OF PRINCIPAL PETROLEUM PRODUCTS, 1899–1920, SHOWING DOMINANT GROWTH OF DEMAND FOR GASOLINE.

Digitized by Google

to depict both the output of crude petroleum and the approximate natural-gasoline content of this output.

The rates of growth of the curves in Fig. 2 may be accurately determined by the method of least squares. The point to be especially noted is that the domestic production of crude petroleum has been increasing at an average rate of 7.6 per cent. a year; the domestic production of gasoline, 21.87 per cent. a year; and the imports of crude petroleum, 72.3 per cent. a year. If this country should continue to import crude petroleum at this rate, the imports for 1930 would be 50.3 billion barrels! Such a statement, of course, is of value merely to emphasize the abnormality of the rate that has characterized the development of the Mexican fields over the past decade; such a rate cannot be maintained for any extractive industry.

Fig. 2 shows a second important relationship, the turning point in the economic status of gasoline that came in 1917, approximately. Prior to 1917, the quantity of crude petroleum produced in the United States contained more gasoline than was required. Since then, the natural gasoline-producing capacity of the domestic output has fallen behind motor-fuel requirements to the degree roughly expressed by the angle between the two curves in Fig. 2. The gap has been filled by imports and a factor that may be designated "new technology," by which is meant cracking, casing-head gasoline, change in end point, etc.

## Empiric Methods of Forecasting Demand

The simplest method of estimating future demand is by projecting current trend into the future. Thus, consumption for a recent period, say the past 10 years, may be plotted, an equation calculated that gives a good fit to the data, and the future consumption for any given date calculated therefrom. Such equations are empiric, determined wholly from the data in the past, and are unreliable for extrapolation beyond the limits of the observations. Empiric methods have the prime advantage of eliminating the personal equation; the results are identical, irrespective of the investigation.

The annual consumption of crude petroleum in the United States for the 10-year period, 1911–1920, are given. The increasing quantity of crude petroleum consumed may be interpreted as an arithmetic growth or else as a geometric progression of even or accelerating rate. First a straight line, then a compound-interest curve, and finally a parabola were fitted to the data by the method of least squares, the equations of these curves determined, and extrapolated values for 1925 and 1930 calculated. The results are given in the straight-line and compound-interest curves shown in Figs. 3 and 4. (Fig. 3 not shown here.)

The domestic consumption of gasoline for the years for which accurate statistics are available is shown. By fitting a straight line to the data by the method of least squares, extrapolated value for 1925 and 1930 may be obtained.

The domestic consumption of kerosene (Fig. 1) displays a recent rate of growth sharply at variance with that of the other petroleum products. For the period 1918–1921, the trend of this item has been downward. Whether this downward trend is temporary or permanent remains to be seen. Accordingly, a straight line has been fitted by the method of least squares, first, to the whole period 1916–1920, and second, to the last three years of that period when the trend was downward.

The domestic consumption of lubricating oils for the period for which accurate statistics are available is shown together with extrapolated values for 1925 and 1930 determined by fitting the equation of a straight line to the data by the method of least squares. As the consumption of lubricating oils is made of two components, industrial oils and motor oils, each growing at different rates, the empiric method of projection given is not apt to yield reliable results.

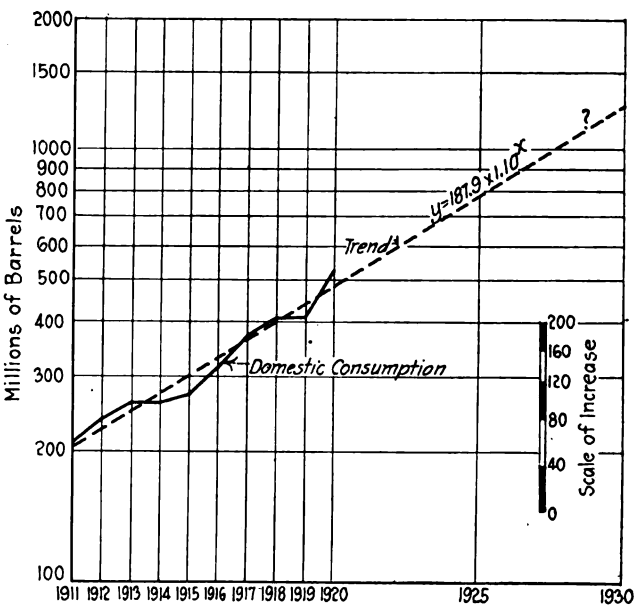

Fig. 4.—Empiric projection of demand for crude petroleum in United States determined by fitting a compound-interest curve to data by method of least squares.

The objection to empiric methods of projection is that, while the results may closely correspond to subsequent conditions, again they may not, and there is no way of telling in advance their reliability in any particular instance.

## Rational Methods of Forecasting Demand

It is the writer's opinion that for the problem in hand, the straight-line projection is more reliable than either the compound-interest curve or the parabola; but that results so obtained must be used with extreme caution, and that, on the whole, empiric methods do not offer a satisfactory solution of our problem.

Although future requirements may be estimated by projecting observed rates of change, by appropriate

Digitized by Google

mathematical methods, no allowance is made for modifying influences that may affect the projected rates of growth. Can such allowance be made scientifically? Can we utilize past data and at the same time introduce factors drawn from outside the data, so as to arrive at sounder results than may be gained from the relatively simple methods thus far reviewed? Fortunately, there are rational methods that hold some promise in this connection.

An estimate of the growth of motor-vehicle registrations to 1940 was recently worked out on the basis of an assumed car density for that year and the results plotted as a projected curve. The projection was calculated by observing that in 1919 the car density in California was one car for every 6.07 persons, in Iowa one car for every 6.12 persons, and in Nebraska one car for every 6.54 persons; assuming that in 1940 there would be one motor vehicle for every 5 persons, the total number of vehicles being equally divided between passenger cars and trucks; making use of the projected curve of population as worked out by the engineers of the New York Telephone Co.; and plotting a smooth curve from the observed data of 1910–1919 to the year 1940, so as to reach the assumed ratio of vehicles to population on that date. The purpose of the investigation was not to forecast results for so remote a period as 1940, but to obtain workable figures for a few years ahead. The theory is that if the assumption of the ultimate ratio is made for a date far enough ahead, even a material error in that assumption would not seriously alter the forecast for the next few years.

According to this projection, there will be in use in 1925 approximately 10,000,000 passenger cars, and 5,100,000 trucks; and in 1930, about 12,200,000 passenger cars and 9,200,000 trucks. If we multiply the number of cars by the average annual consumption of gasoline per unit and make a similar calculation for trucks, we will arrive at an estimate of automotive-fuel requirements for 1925 and 1930, as shown in Table 12 as follows:

(*In millions of gallons*)

| Year | Estimated Consumption by Passenger Cars | Estimated Consumption by Trucks | Estimated Consumption by Cars and Trucks |
|---|---|---|---|
| 1925 | 3,350 | 5,100 | 8,480 |
| 1930 | 4,087 | 9,200 | 13,287 |

The calculation as given above, while having points of interest, is subject to criticism.

R. B. Prescott, of the Class Journal Co., has applied to economic data a formula devised some years ago by Gompertz and well known in actuarial work, which involves the principal of growth at a diminishing rate; or in other words the principle of diminishing returns.

The registrations of motor vehicles in the United States by years for the period 1912–20 are shown on a semi-logarithmic scale in Fig. 7. To the registration figures is fitted a curve of the type, $y = ab^{cx}$, which is projected to 1930. This curve, which is published by permission of Mr. Prescott, is thought to represent the trace of the normal growth of the automotive industry, and, if so, affords a rational basis for forecasting not only future demand for motor vehicles but the future requirements of motor fuel. Curves of this type have been tested on pig iron, potatoes, population, wheat, sugar, steel, railroad mileage, and cotton; and it has been found that the equation, fitted to data up to 1900, when extended to 1920 gave extrapolated values for 1920 corresponding to the actual figures within errors of 0.2 per cent. While the application of this technique is still in its developmental stage, the method gives promise of becoming a useful tool for predetermining the normal growth of industrial activities and market requirements.

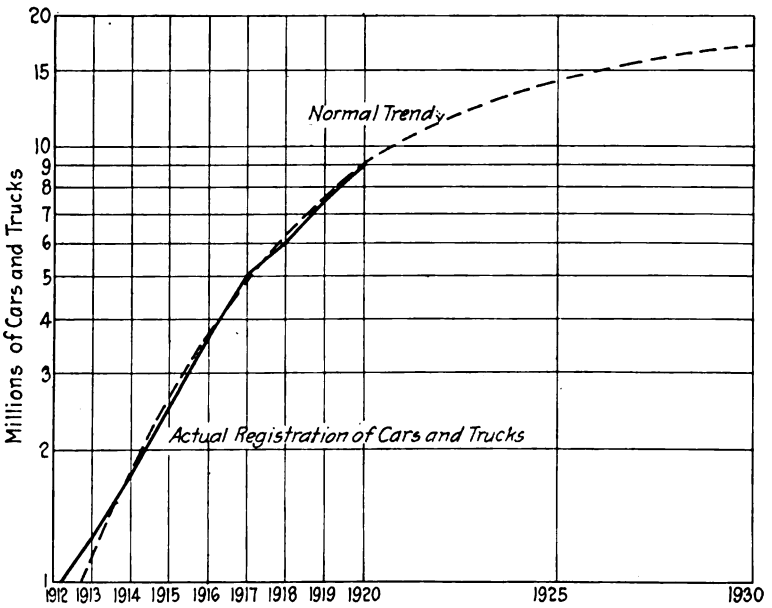

FIG. 7.—PROJECTION OF MOTOR-VEHICLE REGISTRATIONS IN UNITED STATES BY MEANS OF PRESCOTT FORMULA INVOLVING PRINCIPLE OF DIMINISHING RETURNS.

The projection of motor-vehicle registrations, as shown in Fig. 7, indicates clearly that the further growth of automotive transportation will be at a decelerating rate. The projection of the registration figures in this manner gives 14,400,000 motor vehicles (cars and trucks) as the probable number for 1925 and 17,500,000 as the probable number for 1930.

These extrapolated values may be converted into gasoline by multiplying them by the average gasoline consumption per unit (assuming that the consumption factor will not change materially); or else by fitting the normal registration curve to the curve representing domestic gasoline consumption and taking the trace of the former as the probable future course of the latter. The second method projects the ratio between motor vehicles and domestic gasoline consumption and

Digitized by Google

therefore yields figures representing total consumption, instead of the consumption of cars and trucks alone. The results of the two methods are given in Table 13.

TABLE 13.—*Estimated Consumption of Gasoline (And Other Motor Fuels) in United States in 1925 and 1930, Based on Application of Prescott Formula to Automotive Registrations*

| 1 Year | 2 Number of Motor Vehicles, Millions of Units | 3 Consumption of Gasoline[a] by Cars and Trucks, Column 2×400, Millions of Gallons | 4 Consumption of Gasoline[a] by Cars, Trucks, Tractors, etc., Projection of Ratio, Millions of Gallons | 5 Difference, Column 4 minus Column 3, to be Credited to Tractors and Miscellaneous Uses, Millions of Gallons |
|---|---|---|---|---|
| 1925 | 14.4 | 5760 | 6800 | 1040 |
| 1930 | 17.5 | 7000 | 8300 | 1300 |

[a] Gasoline should be read in this table as gasoline and other motor fuels.

Several refinements, theoretically, are possible with this method, but accurate statistical data are available for such a brief period as to render preferable the indirect graphical method shown above. Accordingly, it seems better to let the investigation rest for the time being with the generalized results given in Table 13.

### SUMMARY OF THE SEVERAL METHODS OF FORECASTING GASOLINE DEMAND

A comparison of the results of projecting the future gasoline requirements of the country by the three methods outlined is given in Table 14.

TABLE 14.—*Comparison of Estimated Future Demand for Gasoline in United States (In millions of gallons)*

| | 1923 | 1925 | 1930 |
|---|---|---|---|
| Straight-line projection | 6,101 | 7,347 | 10,462 |
| Vehicle to population ratio | 5,748 | 8,480 | 13,287 |
| Prescott formula | 5,900 | 6,800 | 8,300 |

It will be noticed that while the methods yield widely different results for 1930 they are in reasonably close agreement for 1923. This concordance for the nearer date speaks for the practical value of mathematical methods of projection in general. Emphasis should be again laid on the fact that the need for accurate estimates is greater for the next few years than for a period 5 to 10 years ahead, and all three methods meet this important criterion. The projection by the Prescott formula, however, is given as the most probable estimate of future demand and one that may be used as a working basis for long-range planning.

### CONCLUSIONS

1. The demand for crude petroleum for the next 10 years will be determined by the growth of automotive transportation and the motor-fuel requirements resulting therefrom.

2. Future consumption of crude petroleum and its products may be estimated by methods of empiric projection, and the results attained by such methods are given, but such methods are not regarded as satisfactory.

3. Two rational methods of forecasting the demand for gasoline are described and applied, and a method involving the principle of diminishing returns is advanced as the most satisfactory approach to the problem.

4. By means of the method involving the principle of diminishing returns, the domestic demand for gasoline is estimated to be 6800 million gallons in 1925 and 8300 million gallons in 1930.

5. The ratio between the quantity of crude petroleum consumed and the quantity of gasoline produced is empirically projected, by fitting a straight line to the data by the method of least squares, and according to this method 27.7 per cent. of our crude petroleum consumption will be converted into motor-fuel service in 1925 and 33.9 per cent. in 1930, as contrasted with a percentage of 19.9 for 1920 This projection is subject to a greater probable error than the estimate of gasoline requirements.

6. Combining the results mentioned in the two preceding paragraphs; the estimated demands for gasoline in 1925 and 1930 are converted into demands for crude petroleum. The results attained indicate that 585 million barrels of crude petroleum will be sufficient to support automotive transportation in 1925 and 580 million barrels will be sufficient for 1930, on the basis of a continuation of recent progress in technology.

7. The results attained are subject to more accurate determination on the further development of the methods followed, but the present results are advanced as having sufficient probability to be of practical value as a basis of present planning.

## Spies Open-stope System of Mining*

BY S. R. ELLIOTT, ISHPEMING, MICH.

The Spies mine near the village of Iron River, Mich., is operated by The Cleveland-Cliffs Iron Co. The jasper hanging walls of most of the deposits in the Iron River district dip at a steep angle and are strong, standing without caving, even after mining has been continued for years and after large excavations have been made. The ore is hard and tough and contains no slippage faces. It occurs in large masses, often egg shape, with the smaller end down. It can be mined in open stopes without the use of timber. The Spies system was developed to utilize the advantages of the open-stope method and to avoid the disadvantages of the shrinkage stope.

The Spies shaft was sunk to such a depth that the bottom, or third level, was in rock at a short distance

* This is the entire paper, not an abstract.

Digitized by Google

below the bottom of the orebody, the shape and extent of which had been previously determined by diamond drilling.

In order to provide the necessary mills and raises, three parallel crosscuts were driven on 25-ft. centers on the bottom level. Drifts on the second and first levels were driven to the orebody and followed the foot wall in a southerly direction to the end of the ore. In crosscut 3, Fig. 1, raises 30, 40, 50, and 60 were carried up on the foot wall and holed into the second level, and ultimately carried up and holed into the first level. These foot-wall raises carry the pipes and ladders, provide a means of ventilation, and furnish safe communication to all working places in the stope.

From crosscuts 1, 2, and 3, raises were completed to a height of 32 ft., or the elevation of the first sublevel. They were then connected by east and west crosscuts to the main foot-wall raises 30, 40, 50, and 60, shown in Fig. 4. The crosscuts in raises 1 to 5 were then driven west and the hanging wall located. While this work was in progress, raises 1 to 5, 10, 12, 14, 16, 18 were driven until they reached the hanging wall. At intervals of 22 ft., the raises were connected by east and west crosscuts and the hanging wall to the west was located at the elevation of each sublevel. This is shown in Fig. 2.

Below the 639-ft. sublevel raises 1 to 5 were coned to an angle of about 45° to serve as mills. Miners then started in each crosscut on the 639-ft. sublevel, at points near the hanging wall and made fan-shaped holes toward the same. By repeating this operation on sublevels at higher elevations, the ore was cut away from the hanging wall and a narrow opening existed over the mills in crosscut 1 for the length and height of the orebody. From this time on, to the completion of the stope, the work was straight mining. Miners set up their machines in the various crosscuts at a safe distance from the edge of the open stope and drove holes pointed fan-wise toward the west, care being taken to pull back the east face in a vertical plane.

If one could stand against the hanging wall at a point opposite the center of the stope and look east, this face would resemble, in prospective, a number of pyramid-shaped funnels in a horizontal position, the larger end pointing toward the observer, the crosscuts being the spouts. This is shown in section and elevation in Figs. 5 and 6. While stoping is being continued, it is necessary to complete additional raises and to do crosscutting at higher elevations, or in parts of the orebody farther east.

### Disadvantages of the Shrinkage Stope

1. In a shrinkage stope, after mills have been made, the orebody is undercut. By setting up the machines on the broken ore and working around the perimeter of the stope, its height is increased until the top of the deposit is reached. After each blast, only sufficient ore is drawn from the mills to make room for the miners to work. A safe rule to follow is to have the back above the point where the machines are set up close enough for it to be touched by a miner when his arm is extended. With this precaution, it can be readily trimmed. Further, miners should not be premitted to go out toward the center of the stope, but should be kept close to a solid wall. Observing these rules, and always working around the perimeter, causes large orebodies to remain in the center of the stope which either must be blasted, by the use of long drills, or if they cannot be reached, must be left until they become so heavy that they will fall because of their weight. In time, these large massse are drawn down to the mills, when they must be broken by men who enter the mills from the bottom to drill and blast them; this is slow, expensive, and exceedingly dangerous work.

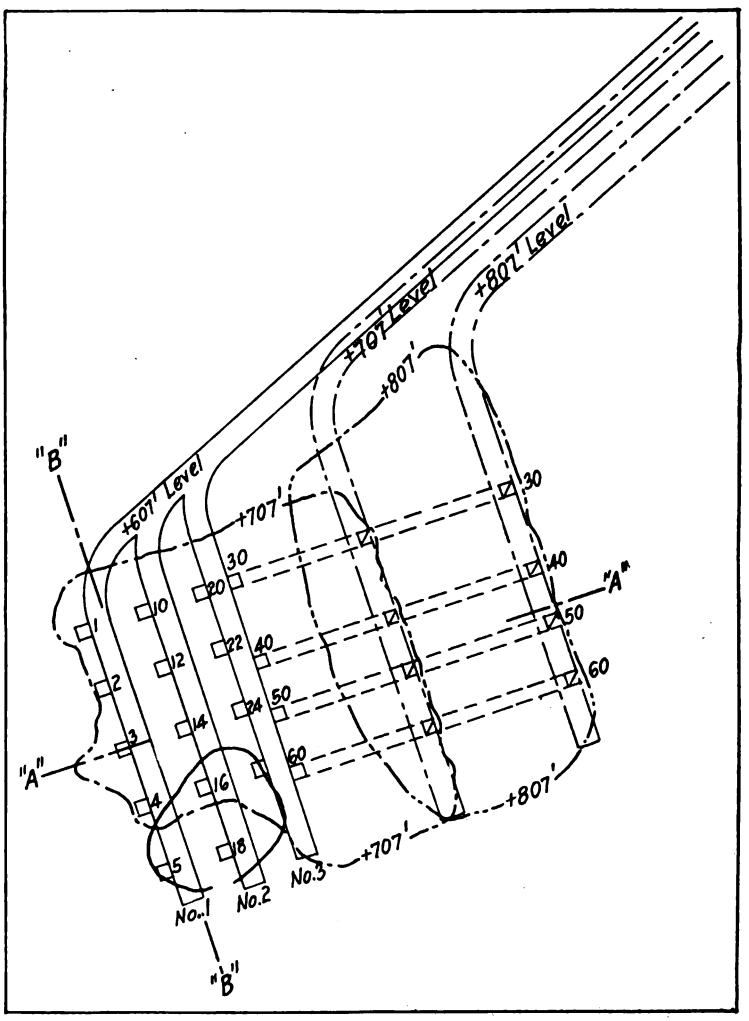

Fig. 1.—Plan of Spies Mine, showing main levels, contours of orebody, raises and mills.

2. As the ore is broken in a shrinkage stope, only about one-third of it can be drawn out of the mills. The pile in the stope must constantly be increased in

Digitized by Google

height until the top of the deposit has been reached and the stope completed. A large investment, represented by two-thirds of the broken ore, is tied up until the stope is completed.

3. The miners spend a large proportion of their time trimming the back, trying to make it safe; their drilling efficiency is, therefore, low.

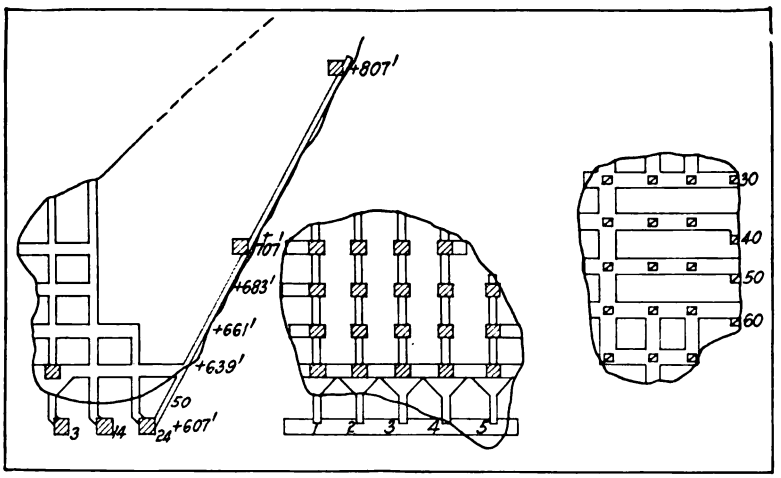

Fig. 2. Fig. 3. Fig. 4.

Fig. 2.—Section A–A before stoping is begun.
Fig. 3.—Section B–B before stoping is begun.
Fig. 4.—Plan of 639-ft. sublevel.

4. In drawing sufficient ore each day to keep the top of the pile at the proper distance from the back, there is constant danger that the ore will not settle properly and later on will surge and endanger the lives of the men in the stope.

5. If seams or bunches of rock are encountered, they must be broken with the ore; there is no means of separating the material.

6. Ventilation, as a rule, is poor and much time is lost after each blast.

### Advantages of the Spies System

The advantages of the Spies system compared in the same order as the disadvantages of the shrinkage stope enumerated are:

1. All men are provided with a safe and easy traveling road to their working places. There is every opportunity for miners to drill their holes with a proper burden on them, so that it is unnecessary to break the ore in large masses. It is not necessary to go up into mills to drill and blast. These are the chief factors that make it possible to obtain low cost by the use of this system.

2. All of the ore broken each day is drawn from the mills, only enough being left to protect the stopers from the shock of falling ore blasted in the stope. An accurate check can, therefore, be kept on the miners and high efficiency obtained.

3. No time is lost in trimming. The men are in no danger from falls of ground so their time is spent in drilling and blasting; their efficiency, therefore, is much higher than in the shrinkage stope.

4. There is no danger that the ore upon which the men are standing will be drawn from under their feet as they work in crosscuts with solid ore below them. Their machines are set up on posts, which is preferable to using tripods on loose ground.

5. During the development work in the sublevels, all seams of rock in the ore are outlined and can be mined before the stope has reached that locality, the rock being dumped into raises that are not being used as mills. It is possible, therefore, to mine the ore and keep it clean.

6. On account of the large number of small raises and the connections with upper levels, no trouble is experienced with ventilation. Blasting can be done at any time during the shift and only a few minutes lost. The area of the open stope soon becomes so large that the gases are rapidly dissipated and pass off through the upper levels.

With the exception of a small thickness of ore left above the first level to support the overburden sand, the stope in the Spies is completed. In this mine, on a comparatively narrow orebody, we have also worked the shrinkage-stope method, and therefore have had an opportunity to make a close study and comparison of the two systems. Our records show that the cost of breaking ore was about 4 per cent. higher in the shrinkage stope than where the Spies system was used. From every point of view, the Spies system has proved more satisfactory than the shrinkage stope.

# Personal Notes and Biographies

**James A. Lane** is sales manager in New York for the Stimpson Equipment Co., Inc.

**George J. Porter** is project engineer with the New Mexico State Highway Commission.

**W. E. Thorne,** who spent part of last year in Europe and Africa, is at home for a short vacation.

**George G. Fleming** is production planning manager with the G. & J. Tire Co., Indianapolis, Ind.

**Bradley Stoughton** has been elected president of the Yale Engineering Association.

**A. B. Needham** has accepted a place on the engineering staff of the Butte & Superior Mining Co., Butte, Mont.

**John Stansfield** recently returned to England. His address will continue to be 115 Edmund Road, Hastings, England.

**Melvin M. Garrett,** recently with the Sinclair Oil Co. at Tulsa, Okla., is now with the Hobbs Oil Co., in Wichita Falls, Texas.

**E. J. Schrader** is making an extended visit in St. Paul, Minn., recuperating from an illness that followed an accident to his eye in the latter part of last year.

**W. H. Wright** is superintendent of the Compañía Minera Chocó-Pacífico, Andagoya, Colombia, S. A. The company is dredging for gold and platinum.

**D. M. Drumheller, Jr.,** returned to the Tidewater Copper Co., Sidney Inlet, B. C., as general superintendent, when that company resumed operations early in February.

**L. M. Kniffin,** formerly manager of the Hanover Bessemer Iron & Copper Co., at Fierro, N. M., is now with Madeira Hill & Co. as development engineer, at Frackville, Pa.

**L. G. Donnelly** has withdrawn from the firm of Brokaw, Dixon, Donnelly, Garner & McKee, geologists and petroleum engineers. The firm will hereafter be Brokaw, Dixon, Garner & McKee.

**Kenneth Williams** has been appointed metallurgist at the Copper Queen smelter of the Phelps-Dodge Corporation. He was formerly general foreman of reverberatory furnaces and roasters at that plant.

**S. F. Shaw,** manager of the Compañia Minera La Constancia in Sierra Mojada, Mexico, is now also superintendent of the properties controlled by the Compañia Minera de Peñoles, in the same district.

**L. K. Armstrong and John C. Semple,** by mutual agreement, have dissolved the partnership of Armstrong and Semple. Mr. Semple has opened offices in the Shoshone Bldg., Wallace, Idaho, for consulting work.

**Colin G. Fink,** electrometallurgist, has opened a consulting office at 101 Park Ave., New York. Doctor Fink was formerly with the General Electric Co. and later in charge of the research laboratory of Guggenheim Brothers.

**Ernest V. Pannell,** who has been acting as consulting engineer and metallurgical expert for the British Aluminum Co., Ltd., in New York during the past two years, is now on his way to take care of the company's business in Tokyo, Japan.

**Frederick F. Sharpless,** secretary of the A. I. M. E., has been elected a corresponding member of the Canadian Institute of Mining and Metallurgy. The term "corresponding member" is used by the Council of the Canadian Institute to indicate complimentary membership.

**J. E. Elliott** and **F. C. Merritt,** consulting engineers and geologists, have an office at 205 South Broadway, Los Angeles. Last year, Mr. Elliott resigned his position as associate professor of petroleum mining at Stanford University, to undertake the special work of taking core samples from oil wells drilled by the rotary method.

---

## Schuyler Lawrence

SCHUYLER LAWRENCE, long a resident of Chihuahua, Mex., where he was a prominent member of the Chihuahua Foreign Club and the first president of the American Society of the State of Chihuahua, died at Mysox, Pa., on Jan. 9, after a long illness.

Mr. Lawrence was born in Topeka, Kansas, in 1864, a son of Warren W. H. Lawrence, then Secretary of State for Kansas, and Sarah Schuyler, daughter of Judge Philip C. Schuyler, a noted Free State leader and president of the Free State convention of 1855. In addition to the Schuylers, Mr. Lawrence had among his ancestors the other well known New York families of Van Rensselaer, Van Cortlandt and Livingston.

At the age of eighteen, Mr. Lawrence went to Mexico with the late A. A. Robinson, in the mechanical engineering department in construction of the Mexican Central Railway from El Paso to Mexico City. After the road was completed, he turned his attention to mining and settled in the city of Chihuahua, his principal operations being on properties in the nearby old camp of Santa Eulalia. Chihuahua claimed him as a resident until soon after the beginning of the Mexican revolutions. At that time, he moved to Mysox, Pa.,

Digitized by Google

where, to keep from rusting, he went into the raising of high-grade apples.

During the World War, Mr. Lawrence was in charge of the Intelligence Bureau of the Mexican Division of the War Trade Board, where his work was of such high character that he was prominently mentioned, at the beginning of the Harding Administration, for chief of the Mexican Division of the State Department—a post finally won by Fletcher, former Ambassador to Mexico.

He married, in 1910, Miss Mary Welles, of Towanda, Pa., and is survived by his mother, his wife and two sons, Schuyler, Jr. and Charles, and a brother, Cortlandt Lawrence of Los Angeles.

Mr. Lawrence was a member of the American Institute of Mining and Metallurgical Engineers and of the American Society of Mechanical Engineers.

## Charles Baskerville

CHARLES BASKERVILLE, director of the chemical laboratories of the College of the City of New York, died of pneumonia on Jan. 28, 1922. Born in Mississippi, June 18, 1870, he studied at the University of Mississippi in 1886 and 1887 and was graduated from the University of Virginia in 1890. He attended Vanderbilt University in 1891, and received the degree Ph. D from the University of Berlin in 1893 and from the University of North Carolina in 1894. From 1891 to 1904 he was connected with the chemistry staff of the University of North Carolina as instructor, assistant professor and professor of chemistry and director of the chemical laboratory. In 1904 he became professor of chemistry at the College of the City of New York.

Doctor Baskerville was a member and councillor of the American Chemical Society, a fellow of the American Association for the Advancement of Science, a fellow of the Chemical Society, London, a member of the Society of Chemical Industry, the American Electrochemical Society, the American Institute of Mining and Metallurgical Engineers, the New York Academy of Sciences, the Franklin Institute, Phi Beta Kappa Society and the Delta Kappa Epsilon Fraternity. His clubs were the Century, Engineers, Chemists' Graduate, City College, Colonado, Southern and Authors'.

An editorial in the New York *Times*, a few days after his death, pays tribute to his work as a scientist and forms a fitting obituary. The *Times* says:

The service, at once scientific and humanitarian, of Dr. Charles Baskerville is illustrative of what the science of chemistry is undertaking for the alleviation of human suffering. Doctor Baskerville's special researches had to do with the causes and prevention of occupational diseases and with the purifying of ether as an anesthetic.

Several centuries ago the chemist and the physician coöperated. Then they separated, the chemist turning toward industrial production. Now it is being realized that, though the bacteriologists and pathologists have accomplished wonders, they have "definitely reached a point where they must turn to the chemists for the solution of many of their most important problems." Not only are the chemists' medicaments needed for the cure or alleviation of certain specific diseases, but their advice is needed as to the acceleration or retardation of chemical reactions that take place in the body. The myriad battles with avoidable or preventable disease there go daily on. The lesson of the war intimates what victories may be expected in these battles from the coöperation, under ideal conditions of time and research, on the part of those whose science touches these very issues of life.

Doctor Baskerville, not only by his own researches, but also and especially by developing and equipping what was perhaps the best series of chemical laboratories in the United States and by organizing a department which has given tuition to hundreds of young men for service in this science, made his lasting contribution, though his studies and researches and teaching here are over. It will be remembered, however, that but a few weeks before his death, after years of intimate study of the atom, he said that "there is something that cannot be explained on a purely materialistic hypothesis." So the quest goes on.

## L. W. Stedman

LOUIS W. STEDMAN was born at Dixton, Ill., in 1861. He was graduated from the high school of that town, and entered Cornell in 1882. He did prospecting work at Fort Steele, B. C., and later went to the Coeur d'Alenes district, Idaho, where he was superintendent and manager for the Paragon Mining Co.

He died of pneumonia, on May 10, 1921, at Valleyford, Wash., and was buried by the Elks Lodge at Spokane. His wife and one son, Donald, survive him.

## Necrology

THE deaths of the following members were reported to the Secretary's office during the month Jan. 14, 1922 to Feb. 18, 1922.

| Date of Election | Name | Date of Death |
|---|---|---|
| 1920 | Baskerville, Charles | Jan. 28, 1922 |
| 1890 | Benson, A. J. | |
| 1917 | Campbell, Donald G. | Dec. 18, 1921 |
| 1920 | Hoyt, Donald C. | Dec. 27, 1921 |
| 1920 | Lannon, James A. | Jan. 21, 1922 |
| 1915 | Reed, Hubbard W. | Jan. 30, 1922 |
| 1910 | Selbie, Charles C. | March 1921 |
| 1917 | Stedman, L. W. | May 10, 1921 |
| 1917 | Vance, Stratton | Aug. 1921 |
| 1917 | Whitney, L. H. | Dec. 17, 1921 |

# Institute Affairs

## Honorary Membership in Foreign Societies to A. I. M. E. Members

SIR John Cadman was the guest of the Board of Directors of the A. I. M. E. at the dinner preceding the meeting of the Board on Dec. 16, 1921. Sir John served with his government during the war as an expert on petroleum and it is in this connection that he is now visiting the United States. In addition to his technical engagement, he was commissioned by the Institute of Mining Engineers, of which he is president, and the Institution of Mining and Metallurgy, to present certificates of Honorary Membership to the president of the Institute and the members of the John Fritz Medal delegation to Europe in June, 1921.

A list of all the honorary degrees conferred was printed in a previous number of MINING AND METALLURGY in accordance with cable information. Owing to a slight inaccuracy in the cable, this list as printed did not represent the list of degrees as finally conferred. They were as follows:

| | |
|---|---|
| Iron and Steel Institute | Charles F. Rand |
| Institution of Mechanical Engrs. | Ambrose Swasey |
| Institution of Mining Engrs. | Ambrose Swasey |
| Institution of Mining Engrs. | William Kelly |
| Institution of Mining and Metallurgy | Arthur S. Dwight |
| Institution of Mining and Metallurgy | Edwin Ludlow |
| Society of Civil Engrs. of France | Ambrose Swasey |
| Society of Civil Engrs. of France | Herbert Hoover |
| Officer of Legion of Honor | Ambrose Swasey |

In conferring these certificates, Sir John made the following felicitous remarks:

### Edwin Ludlow

In you, Mr. Ludlow, we on the other side recognize a man of great ability, distinction and character. Your early pioneer and reconnaissance work in railway engineering is well known to us, and your activity and thoroughness which you have displayed in the development of coal mining, in which you have brought to play scientific methods, have marked you out as a man amongst men.

The positions of great responsibilities which you have held bear testimony to your greatness in the profession of mining engineering.

To you as president of the American Institute of Mining and Metallurgical Engineers, occupying the most dignified and highest office which your fellow engineers can bestow upon you, we desire to show our personal appreciation and admiration. At the same time we wish to convey through you to the great profession which you so ably adorn our good will and enduring friendship, and also to congratulate you on the occasion of the Institute's Jubilee.

We recognize the great and excellent work which your institution has already accomplished and is accomplishing, and we desire to raise our voices in praise of the unremitting energy, ability and learning which you are displaying in the interest of science in those vast fields of mining and metallurgical activities over which this institution plays such a powerful and important part.

As the distinguished president of the American Institution of Mining and Metallurgical Engineers, as a man of great attainments in the profession, I am privileged to present to you the diploma of Honorary Membership of the British Institution of Mining and Metallurgy.

### Colonel Arthur Smith Dwight

You were one of the delegation that visited Europe and carried the message that touched the hearts of British engineers. In you we recognize a man of great qualifications and great talents. We have long followed your distinguished career and we recognize in you an example of those sterling qualities of learning, activity and uprightness which is a characteristic of your great race.

As an engineer, inventor and scholar you have won a high place not only in your own country but amongst the engineers of the whole world, and as a soldier your activities rank second to none in your devotion to duty and gallantry in the cause of freedom and honor. You served as Major in the 11th Engineers, which with hardly any other weapon than the pick and shovel, thrilled the Allies by the noble and brilliant service at Cambrai on that memorable Nov. 30, 1917. For your great service in the war my country was pleased to confer on you the Distinguished Service Order. For your distinguished service in the science and art of mining engineering, I am deputed by the Institution of Mining and Metallurgy of Great Britain to hand to you the highest honor which it is our privilege to bestow—that of Honorary Membership in that body.

### William Kelly

Your work as a mining engineer is so well known and so varied that it would be impossible for me to touch upon the many phases of your activity in the pleasant task which has fallen to my lot to perform on behalf of the mining engineers of Great Britain. We recognize in you a mining engineer whose experience and ability places you amongst the highest in the profession.

We were honored in welcoming you in England as a delegate conveying the message which the American engineers were kind and generous enough to send to British engineers, and we appreciated to the full the warm and touching manner in which you personally played your part.

We desire to show our deep appreciation and cordial thanks to you and those who were associated with you in the kind thoughts which prompted that mission, and we wish to honor you as a man of attainments and ability in every way fitted to receive and to convey our lasting admiration to your great engineering profession. On behalf of the Institution of Mining Engineers of Great Britain, I have pleasure in presenting to you the diploma of the Institution of Mining Engineers.

### Another Feature of the Dinner

Another interesting feature of this last dinner of the outgoing administration was its tribute to the retiring and incoming presidents by W. L. Saunders who said:

As this is the last one of these delightful monthly dinners prior to the Annual Meeting of the Institute, it seems fitting, and to me it is a pleasure to say a word about him who is to go out of office as president of the Institute and him who is to come in.

I noticed your enthusiasm a moment ago when we drank to the health of Ludlow. It is also apparent that Ludlow has gained in popularity. Witness the large attendance at this dinner, requiring side tables to accommodate the crowd. This recalls to my mind an incident over in New Jersey when a Mayor was elected on the Democratic ticket. At the time of his going out of office they held a dinner and after the dinner a colored gentleman shook the hand of the Mayor and said: "Mr. Mayor, when

Digitized by Google

you was elected some of us colored people voted for you, but now that you are going out we are all unanimous for you."

Some of us who are ex's—and I use the word ex somewhat in the light of extinguished—some of us extinguished presidents, while we may not have much power in the Institute just now, yet have had a lot of experience and through that experience we watch with a jealous eye the work of our successors. I have been watching Ludlow, and I confess that as president of this Institute he has been a past master in the activity of his mind and service, digging into the affairs of the Institute and planning its betterment. He has been totally absorbed by the work of the Institute. His very excellent wife told me the other day that it is the first time since their marriage that she has had occasion to be jealous of anybody or anything; that Ludlow has the Institute on his mind day and night,—so much so that she is becoming alarmed lest he forget that he is a married man. He has already forgotten all he knew about coal.

President Ludlow has brought into the activities of the Institute a practical mind, combining the engineer and business man, a sense of duty and a knowledge of economics that cannot fail to produce wholesome results. Long life to you, Mr. President! May you continue to prosper in ever increasing health, happiness and enjoyment!

As to him who is to come:

> Our hopes, our fears,
> Our love, our tears,
> Are all with you, are all with you.

He can well take care of himself for he is a Colonel. Colonels always take care of themselves, even in battle. When another distinguished Colonel, William Jennings etc., enlisted in the Spanish War his wife approached him in tears as he stood before her in uniform with the eagle on his shoulder and said: "I don't want you to go away. I am afraid you will be killed." The eminent William Jennings replied: "Did your ever hear of a Colonel being killed in battle?"

Well, we all hope that Colonel Dwight will survive the battles of the Institute. We all know that long before America entered the war he first, as a member of the Military Engineering Committee, sat in a board room and gave his time and effort to the cause of preparedness. It was Colonel Dwight, with others, who organized an Engineers' Regiment, equipped at private expense, and sent across the water to aid in the great cause of humanity. We all know how well they performed, and no one did more than Colonel Dwight, who was awarded the Distinguished Service Order.

We are proud to have such a president and we are happy in making the prediction that the Institute under him will continue to grow as one of the strong arms of the engineering profession.

---

## American Engineering Standards Committee and its Work

THE American Engineering Standards Committee essays to serve as a national clearing house for engineering and industrial standardization, to act as the official channel of coöperation in international standardization, and to provide an information service on engineering and industrial standardization matters. The ultimate responsibility for and control of the work rests with the organizations whose representatives constitute the American Engineering Standards Committee. At present these include five departments of the Federal Government, nine national engineering societies, and fourteen national industrial associations.

The Committee functions as a clearing house rather than as a creator of standards.

At the time of the organization of the Committee, there were more than one hundred organizations publishing engineering standards, most of which were formulated without systematic methods of coöperation between the organizations concerned. At the present time 145 organizations are actively coöperating in the work of the Committee, having appointed accredited representatives to serve on section committees.

The function of the main Committee is merely to assure each body or group concerned in a standard an opportunity to participate in its formulation, which is in the hands of a so-called "sectional committee," made up of representatives designated by the various bodies interested.

Such bodies are known as "sponsors." This plan makes the Committee the most decentralized of all the national bodies.

### Method of Work

For some years, the unification and approval of existing standards will necessarily form an important part of the Committee's work. The most satisfactory way of determining the status a standard has in industry is to submit it to a duly organized sectional committee. Before acting on the approval of a standard submitted, a notice of its submission is sent to the technical press, and to the industrial associations and technical bodies interested, requesting information as to the standard in meeting the needs of industry, and the matter is referred to a special committee for investigation. This special committee often contains accredited representatives of those bodies most concerned with the standard, in order that the spirit of the sectional committee method may be carried out.

The A. E. S. C. is not an initiating body and work on a project is undertaken only upon a formal request from a responsible body, and then only after the Committee has assured itself that it is the desire of the industry that the work should go forward.

On account of the great diversity in the lines of standardization activities of the bodies coöperating in the A. E. S. C. work, the coördination of all of them by means of clearing house methods involves the handling of a large number of separate projects. If it is the desire of any industry to have a general committee representative of the industry as a whole, as a means of developing and correlating the standardization work of the industry, such a general correlating committee is set up.

The General Correlating Committee for Mining Standardization has completed its organization and has brought about the spirit of coöperation between the several bodies interested in standardization in the mining field, and developed the methods necessary for carrying out the coöperative work. The schedules of the Bureau of Mines on safety rules for electrical equipment in bituminous coal mines, storage batteries for use in gaseous mines and portable electric mine lamps are being reviewed by sectional committees, the first under the joint sponsorship of the Bureau of Mines and the American Mining Congress, and the last two under the sole sponsorship of the Bureau of Mines. The Correlating Committee has under con-

Digitized by Google

sideration the general subject of the technical provisions of basic mining laws and regulations.

Of the total net income for 1921, approximately 70 per cent, or $17,208.33, was from the dues of the member bodies, $500 annually for each representative on the Committee, with the exception of the Government Departments, which have not yet been authorized by Congress to contribute their share of the expenses of the Committee. During the year financial support to the amount of $5575 was received from companies interested in standardization, as a result of appeals made by the Finance Committee, and $1850 through the efforts of Stanley G. Flagg, Jr.

The present income is not sufficient to provide adequately for the work now before the Committee. The work requested by the industries is increasing rapidly. It has doubled in the last year. A committee on ways and means has been appointed to formulate a comprehensive plan to meet the situation.

GEORGE C. STONE.

## United Engineering Society *

IN THE affairs of the Founder Societies, events of unusual interest occurred during 1921. Important renewals and improvements were made in Engineering Societies Building. Reductions in prices for some commodities conduced to slightly lower operating costs. By strict regard to economy in every detail, our income was made adequate to cover maintenance and operation and to provide for the required addition to the Depreciation and Renewal Fund, but not sufficient to allow payments into this fund to make up the deficiency of last year and other preceding years.

In April, Calvert Townley resigned as trustee representing the Electrical Engineers, vacating the office of first vice-president and the chairmanship of the Finance Committee. W. L. Saunders, second vice-president, was elected first vice-president and appointed chairman of the Finance Committee. Irving E. Moultrop was elected second vice-president.

Superintendent Osterberg lost his life as the result of an automobile accident in August, and Alexander S. Diven, formerly office manager for the Mechanical Engineers, was chosen to fill the vacancy, beginning Sept. 1.

### SEVENTY-FOUR THOUSAND ENGINEERS REPRESENTED

The membership of the four Founder Societies at the end of the year was 49,938, and of the Associate Societies 24,603, so that a total of 74,541 engineers have headquarters in our building. Other technical societies holding meetings in the building have a large aggregate membership in addition.

Upon application by United Engineering Society to the Carnegie Corporation for financial assistance on behalf of the Library, an appropriation of $10,000 a year for two years was made by the Corporation, for extraordinary library expenses, beginning July 1, 1921.

National Electric Light Association informed United Engineering Society that its National Executive Committee had voted an appropriation of $1000 to the Library in response to our request.

A special appropriation of $1250 each toward expenses of the Library for the past year was made by the Civil, Mining, and Mechanical Engineers.

### ENGINEERING FOUNDATION

The annual income of the Foundation is now at the rate of $25,000. The accumulated unexpended balance on Dec. 31, 1921 was $12,958.33. Close relations with National Research Council and contributions to the support of its Division of Engineering were continued. On Oct. 1, Alfred D. Flinn, secretary of the Foundation, was elected also chairman of the Division of Engineering of National Research Council.

Important research projects have been assisted, both directly and coöperatively with the Research Council. Among these may be mentioned: the National Advisory Board on Highway Research, Fatigue of Metals, Industrial Education and Training, Graphitic Corrosion of Cast Iron, Personnel Research Federation and Paint-on-Wood Research.

Work under the agreement of the Foundation with National Research Council and the University of Illinois, on the investigation of the fatigue phenomena of metals, has been completed and a full report printed as Bulletin 124 of the Engineering Experiment Station of the University of Illinois. A publication on this subject soon to be issued by the Foundation is being prepared.

### ENGINEERING COUNCIL AND JOHN FRITZ MEDAL BOARD OF AWARD

At the beginning of the year, the business of Engineering Council was turned over to the new American Engineering Council. It was voted to pay to J. Parke Channing the unexpended balance of funds remaining in the treasury of United Engineering Society to the credit of Engineering Council, at the final closing of the Council accounts, in full settlement for funds advanced under his guarantee for certain expenses. Two of the Founder Societies, the Civil and the Mechanical Engineers, through United Engineering Society, reimbursed Mr. Channing for their pro rata share of the money that he advanced for Engineering Council.

The John Fritz Medal Board of Award, composed of representatives of the Founder Societies, awarded the medal for 1921 to Sir Robert A. Hadfield "for the invention of manganese steel," and for 1922 to M.

* Excerpts from report for the year 1921 by J. VIPOND DAVIES, President.

Digitized by Google

Charles Prosper Eugène Schneider "for achievement in metallurgy of iron and steel; for development of modern ordnance, and for notable patriotic contribution to the winning of the Great War."

### Visit of Marshal Foch

Ferdinand Foch, Marshal of France, and after March 25, 1918, Generalissimo of the Allied Armies in the World War, in America as the guest of the American Legion., visited Engineering Societies Building to receive a certificate of honorary membership in the four Founder Societies.

### Alfred Noble Memorial

The American Institute of Consulting Engineers presented to United Engineering Society a bronze tablet commemorating the achievements of Alfred Noble.

### Resolutions Presented to Doctor Durand

Dr. W. F. Durand was present as guest of honor at the November meeting to afford opportunity for the Founder Societies and the Society of Naval Architects and Marine Engineers to present resolutions expressing appreciation of his services as chairman of the Committee on Management, of the International Engineering Congress of 1915, in connection with the Panama Pacific International Exposition at San Francisco.

### Finances

| | |
|---|---|
| The income of U. E. S. for 1921 was | $117,009.93 |
| The expenses were | 101,370.21 |
| Balance for the year | 15,639.72 |
| This balance includes $6,724.73 in accounts receivable, and $125 uncollectable accounts written off Dec. 31, 1921. | |
| *Funds held by U. E. S. Dec.* 31, 1921 (Book Values) | |
| Engineering Foundation | $502,066.05 |
| Library Endowment | 93,351.25 |
| General Reserve | 10,000.00 |
| Depreciation and Renewal | 98,639.47 |
| Total | 704,056.77 |
| The real estate owned by U. E. S. cost to Jan. 1, 1921 | $1,957,354.31 |
| Permanent addition to building during year | 1,786.36 |
| Cost to Dec. 31, 1921 (cannot be reproduced for that sum) | $1,959,140.67 |
| Total net assets | $2,689,834.75 |

### Changes in Board Membership

In April, the resignation of Calvert Townley, trustee representing the American Institute of Electrical Engineers, was presented and accepted with regret. Henry A. Lardner was appointed his successor.

The new members joining the Board of Trustees during the year were: Arthur P. Davis, representing A. S. C. E.; Edwin Ludlow, representing A. I. M. E.; Worcester R. Warner representing A. S. M. E.; H. H. Barnes, Jr. representing A. I. E. E.

The members retiring by rotation at the end of this year are: J. Vipond Davies, representing A. S.C. E.; W. L. Saunders, representing A. I. M. E.; Irving E. Moultrop, representing A. S. M. E.; Bancroft Gherardi, representing A. I. E. E.

---

## Plan and Scope of Engineering Societies Library

THE Engineering Societies Library was founded in 1913 to meet the need for an engineering library equipped to aid efficiently in engineering research and professional practice. In spite of the rapid growth of libraries in America during recent years, no such institution existed. The university and college libraries, while often rich in material, lacked facilities for making it available. The public libraries usually could not maintain engineering collections of satisfactory scope nor employ custodians with special training in engineering.

Consideration of the needs of the engineer led to the conclusion that these could be best and most economically satisfied by the establishment of a library for the profession, directed by engineers, and administered with their special needs in view. Broadly speaking, the conception was of a complete collection of engineering literature, so arranged, catalogued and indexed that whatever had been printed on any matter could be found with the minimum effort and least loss of time. With this ideal as the goal, the Engineering Societies Library was founded.

As the Engineering Societies Library was organized through the coöperation of the American Institute of Mining Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers, the union of their individual libraries gave at once a collection of great practical value, covering not only mining, machinery and electricity, but many allied subjects as well. In 1916 the American Society of Civil Engineers became a fourth Founder Society, and its library, the oldest engineering library in the country, added much important material to the collection.

It was realized that many engineers have no opportunity to visit the library and carry on personal searches for information, and that if these engineers are to be benefited some arrangement must be provided by which its resources can be available at a distance; and the necessity of providing suitable means for doing this has been kept in mind.

The program toward which the Library Board looks has a vast scope; summarized, these plans include:

1. A book collection covering engineering and the allied sciences, as complete as possible.

Digitized by Google

2. Catalogs, indexes and bibliographies making the information in these books accessible at once.

3. A staff of skilled searchers and translators, available for special investigations.

4. Devices for copying documents.

5. A lending library.

6. Published guides to engineering literature, abstracts, bibliographies, etc.

Work has been in progress along the first four of these lines since the beginning.

---

## Meetings of Directors

A REGULAR meeting of the Board of Directors was held at Institute headquarters on Dec. 16, 1922. Before the meeting began, Sir John Cadman presented certificates of honorary membership to Messrs. Ludlow, Dwight and Kelly (see page 63).

Ferdinand Foch was elected to honorary membership by a unanimous vote of all Directors present. The report of the Committee on Membership containing the names of 98 candidates for membership in various classes was approved.

Colonel Arthur S. Dwight presented a letter announcing that Columbia University extended to the Directors of the Institute the privilege of naming a recipient of a scholarship in mining or metallurgy in the School of Mines, Engineering and Chemistry beginning with the year 1922–23. This scholarship pays $350, about the amount of the annual tuition fees. The offer of Columbia University was accepted and referred to the Committee on Scholarships, which was instructed to coöperate with the Woman's Auxiliary in seeking a suitable candidate for appointment.

The Princeton Engineering Society and the Crucible Club of the University of Nevada were recognized as Affiliated Student Societies.

George C. Stone submitted a report on the work of the American Engineering Standards Committee, with which the Institute coöperates.

Amendments to the By-Laws, published in the January number of MINING AND METALLURGY, were adopted.

After completion of formal routine business, the meeting adjourned.

At the meeting of the Board held on Jan. 27, the Treasurer and Finance Committee submitted a report for the year 1921 showing an available balance to be carried forward of $37,934.78 which will be chiefly used in publishing the papers presented in 1921.

The Finance Committee submitted a budget showing estimated receipts for the year 1922 of $204,534.78 and estimated expenditures of $203,875.00. This budget was referred to the new Board of Directors with the recommendation that it be adopted.

The names of Henry S. Munroe and R. J. Frecheville were placed upon the Honor Roll of Senior Members by unanimous vote.

The New York Section presented a resolution respecting the licensing of engineers in New York State, which was favorably acted upon by the Board. This resolution was published in the February issue of MINING AND METALLURGY.

Following the approval of the resolutions of the New York Section, a resolution respecting the licensing of mining engineers throughout the United States was offered by President Ludlow. This resolution was adopted in the following form:

WHEREAS the Licensing and Registration Laws have been already enacted in twenty of the States and are being proposed for enactment in a number of other States;

AND WHEREAS the results of the operation of these laws in the States where they are now in force have proved that they are not advantageous to the profession of Mining Engineering, but that, on the contrary, the restrictions requiring separate licenses in each State are unnecessary and burdensome to a profession the members of which are likely to be called upon to practice in many different States in the course of a year;

AND WHEREAS it has been further shown that licensing of Mining Engineers brings an added danger to the public in the States where licensing laws have already been passed, as persons calling themselves mining engineers, but without the proper experience and judgment, have been able to pass the rather superficial examinations and obtain licenses and have been employed by unscrupulous promoters, who advertise the fact in their prospectuses that the property they are placing before the public has been approved by a licensed engineer.

THEREFORE BE IT RESOLVED that the Board of Directors of the American Institute of Mining and Metallurgical Engineers hereby protests that Mining Engineers should not be included in the list of engineers who are required to obtain State Licenses;

AND BE IT FURTHER RESOLVED that in States where Licensing Bills are now being introduced, a committee of our members residing in that State shall be asked to appear before the proper Legislative Committee to urge that Mining Engineers be omitted from the provisions of any proposed legislation;

AND BE IT FURTHER RESOLVED that in States where licensing laws are now in effect, Local Sections of the Institute residing in that State be requested to petition their Legislatures to amend the licensing law in force so as to omit from its provisions the Mining Engineers.

IT IS FURTHER RESOLVED that this resolution shall be published in MINING AND METALLURGY for the information of our members, and that copies of this resolution be mailed to the Chairman and Secretaries of our Local Sections.

The reports of our representatives on American Engineering Council and that of the Joint Committee on Code of Ethics were received. The latter is published in this issue. (See page 46.)

Representatives were appointed to attend a conference in Philadelphia respecting the holding of an Engineering Congress in that city in 1926.

---

## Institute of Metals Division Summer Meeting

PAPERS to be presented at the summer meeting of the Institute of Metals Division must be sent to the office of the Secretary of the A. I. M. E. not later than March 24. The meeting of the Institute of Metals Division will be held in Rochester, June 5–9, in connection with the meeting of the American Foundrymen's Association.

Digitized by Google

# Activities of Other Societies

## A. S. C. E. 69th Annual Meeting

THE American Society of Civil Engineers held a most successful meeting in New York on Jan. 19–20. National Transportation Problems, subdivided into Water Transportation, Railroad Transportation, etc., furnished the topics for the sessions in the Engineering Societies Building. Excursions were made to the McGraw-Hill Publishing Co., the Stock Exchange, and several other points of interest, and there were many social gatherings.

Honorary membership was conferred on Eugène Schneider, Luigi Luiggi, Samuel Rea, Ambrose Swasey and Howard A. Carson.

## Electrochemical Spring Meeting

ONE of the papers to be presented at the meeting of the American Electrochemical Society, Apr. 27–29 in Baltimore, Md., is by Dr. Duncan MacRae of the Westinghouse Research Laboratory, and describes a new method for determining the pressure in a tungsten vacuum lamp. The principle is simple and more accurate than the approximation that has heretofore been made by the use of the induction coil. The pressures are measured by a McLeod gage. The measurements on lamps immediately after the process of exhaust (before "flashing"), and after "flashing," as well as on life tested lamps, are given. The operation known as "flashing" consists in lighting the lamp during exhaust in the presence of phosphorus or other chemical substance.

The Society is planning three sessions, on Electric Furnace Cast Iron, Gases of the Electrochemical Industries, and Electromotive Chemistry.

## Taylor Society Meeting

THE tentative program for the meeting of the Taylor Society to be held in Philadelphia, March 16–18, includes papers on:

A Case of Sales Research, by John M. Holcombe, Jr., Manager Sales Research Division, Phoenix Mutual Life Insurance Co., Hartford, Conn.; Problems of General Management, by Henry P. Kendall, of Boston; Super-standards, by Frank B. and L. M. Gilbreth; Budget Control, by George E. Frazer, of Chicago; Mills, Minds and Men, by Arthur Pound, author of the articles, "The Iron Man," now appearing in the *Atlantic Monthly;* String-Board Graphics, by Percy S. Brown, works manager, Corona Typewriter Company; Work of the Balance of Materials Clerk, by Thomas W. Mitchell, of Philadelphia.

## A. A. A. S. June Meeting

THE American Association for Advancement of Science will hold a meeting in Salt Lake City, from June 22 to 24, conjointly with the Pacific Division of the Association. Arrangements will be mainly in the hand of the Pacific Division, the secretary of which is W. W. Sargeant, Golden Gate Park, San Francisco, Calif. The permanent secretary's office in Washington will assist. All members of associated societies are invited to attend.

## American Welding Society Proceedings

THE American Welding Society, which was established in 1919, has begun to issue Proceedings, the first number bearing the date of January, 1922. The American Welding Society is organized to provide united and coöperative action in extending the knowledge of the art of welding and its field of industrial application. The field for further application of welding is enormous, and progress in it is being delayed only by incomplete knowledge and by the confusing and opposing claims of competing interests.

The Society acts as a clearing house for information. Through papers and monthly meetings of local sections, an opportunity is created for the individual manufacturer, engineer, plant superintendent, foreman or operator to contribute his own knowledge in welding and at the same time receive the benefit of the combined knowledge and experience of all other members of the Society. Special publications in addition to the regular monthly Proceedings are issued from time to time, giving results of researches, standardization work and other information of value to the members. The offices of the society are at 33 West 39th St., New York City.

# Local Sections and Affiliations

## New Officers of New York Section

ABOUT ninety members and guests attended the annual meeting of the New York Section, on Feb. 8. The following officers were elected: chairman, Robert Linton; vice-chairmen, Robert M. Raymond and Donald M. Liddell; secretary-treasurer, E. L. Gruver; committeemen, B. Britton Gottsberger and Bradley Stoughton.

## Electrothermic Metallurgy of Zinc

AN illustrated talk on the electrothermic metallurgy of zinc was given before the Ohio Section by Prof. C. H. Fulton, director of the Missouri School of Mines, at its meeting on Jan. 20. Sixty members were present. Before the talk the question of meeting with the Cleveland Engineering Society was discussed.

## St. Louis Section Entertained by Mr. Thacher

THE St. Louis Section held a very enjoyable meeting on Thursday evening, Feb. 9, at the home of Arthur Thacher. About fifty members and guests were entertained.

The chief topic of the evening was Collective Bargaining: Does It Best Serve the Interest of the Public, the Investor, the Employee? The speakers were W. K. Kavanaugh, Eugene McAuliffe, Philip N. Moore, and Arthur Thacher. The meeting was informal and there was interested general discussion.

## Aluminum and Its Alloys

IN HIS talk at the January meeting of the Boston Section, R. H. Pomeroy, of Cleveland, vice-president of the Institute of Automobile Engineers, discussed the suitability of aluminum for general engineering constructions, from the point of view of its low specific gravity and its capacity to sustain loads by virtue of extended dimensions; its suitability for replacing malleable-iron and steel castings; the use of forged aluminum for highly stressed parts; the economic aspects of its use because of its capacity for being rapidly machined.

Just before this talk, Robert J. Anderson, metallurgist of the Bureau of Mines, gave an illustrated talk in which he described the discovery and history of aluminum its development and present application, and the peculiar properties of its alloys.

## Kingman Section Second in Arizona

KINGMAN has the distinction of having the second chapter of the American Institute of Mining and Metallurgical Engineers in Arizona. The section was organized at a meeting of representative mining engineers of Mohave County on Feb. 9. Officers were elected as follows: Roy Moore, of Oatman, chairman; R. S. Billings, of Kingman, vice chairman, and secretary-treasurer; these officers, with W. B. Phelps, of Oatman, S. Ford Eaton, of Chloride, and R. C. Jacobson, of Kingman, compose the governing board.

There are more than 50 engineers in Mohave county eligible to membership in the local chapter. The committee on membership is planning a campaign which will be submitted to the local chapter for sanction at its next meeting.

One of the first official acts was to pass a resolution inviting Herbert Hoover, Secretary of Commerce, to visit Kingman as a guest of the section during his contemplated trip to dam sites along the Colorado river.

## Zinc and Copper Discussed by Colorado Section

AT THE annual meeting of the Colorado Section, on Feb. 4, Robert Hursh read an interesting paper on the "Application of Zinc to Modern Industry," in which he urged all present to do all they could to increase the use of metals. He exhibited a number of articles made from zinc and brass, also a copper shingle made by the Anaconda Copper Mining Co. Afterwards, the secretary read a paper, "Copper a Metal of Commerce," that had been sent by the Anaconda Copper Mining Co.

This meeting was preceded by a dinner at which 65 members and guests were present. After the dinner the following were elected as officers for the ensuing year: Robert Hursh, chairman; J. C. Roberts, vice-chairman; Horace F. Lunt, secretary-treasurer; Max W. Ball and Charles N. Bell, additional members of executive committee. Mr. Hursh was appointed delegate to Colorado Engineering Council.

Digitized by Google

## Underground Workings of Star Mine Studied by Columbia Section

AT THE February meeting of Columbia Section, F. W. Callaway, engineer for the Bunker Hill and Hecla mines, exhibited a model of the Star mine and explained the underground workings. W. G. Woolf then explained the process of zinc and lead metallurgy, illustrating his talk with samples of the crude ore, intermediate, and final products of the Star mine.

A committee was appointed to formulate a report on the present status and possibilities of economic production of petroleum in the vicinity.

The executive committee of the section consists of Rush J. White, chairman; F. M. Smith, vice-chairman, Ivan de Lashmutt, past chairman; L. K. Armstrong, secretary-treasurer; Francis A. Thomson.

---

## Tulsa Section Protests Interior Department Ruling

CONSIDERABLE interest has been created recently in regard to the policy of the Osage Council in matters pertaining to the methods used in the sale of oil and gas leases and method of determining the value of leases offered for sale by the Osage Council in Osage County, Oklahoma.

At the last sale held under the supervision of the Department of the Interior, bids were rejected the day following the sale. Upon the advice of a geologist detailed by the U. S. Geological Survey to advise the Osage Council, the Tulsa Geological Society has passed resolutions protesting this action and has forwarded copies to Washington to the Secretary of the Interior, the Director of the Geological Survey, and to the Chief of the Osage Indian Council.

The Tulsa Section of the American Institute of Mining and Metallurgical Engineers prepared the following resolution along similar lines;

WHEREAS, During the past decade the science of geology has maintained a steady effort to win the confidence of the petroleum industry and has finally, through the force of results obtained, come to be looked upon as an integral and increasingly valuable part of that industry, and

WHEREAS, The faith of the industry in geological service is clearly demonstrated by the large sums of money being spent by the operators in securing expert geological advice and by the increasing numbers of individuals and companies who are shaping their policies to conform to the guidance of their geologists and engineers, and,

WHEREAS, The work of the geologist and engineer has been an important factor in the wonderful development of the Osage Nation, Oklahoma, and has had a marked influence upon prices paid at public auction for leases therein, and,

WHEREAS, The Osage Council has refused to accept bone fide bids made openly at public auction for Osage tracts, the said bids being made by reputable and established operators acting generally upon the advice of their geologists and engineers, and the impression prevails that these rejections were made at the advice of a representative of the United States Geological Survey, and,

WHEREAS, The said rejection of bids has placed the geologists and engineers in the employ of petroleum operators in the position of being in controversy with the official geologists of the United States Government, in regard to the valuation of oil and gas lands, and

WHEREAS, This situation has caused much adverse comment, and has been the basis of much criticism, of the United States Geological Survey and the Osage Council, for having rejected the highest bid.

BE IT THEREFORE RESOLVED, That the Tulsa Section of the American Institute of Mining and Metallurgical Engineers expresses its entire disapproval of the principle of review by the Osage Council upon geological advice of bids made at public auction of Indian land unless there is announced previous to the sale a minimum price which will positively be accepted, or it is made known at the time of announcement of the apparently closing bid on any one tract that the bid is below the minimum value and that the tract may be withdrawn.

RESOLVED, That copy of the resolution be forwarded to the Secretary of the Department of the Interior, to the Chief of the Osage Council, and to the Director of the United States Geological Survey.

This was signed for the Tulsa Section of the American Institute of Mining and Metallurgical Engineers, by Charles T. Kirk, J. R. Pemberton, and William J. Millard.

It was approved of and signed by the Executive Committee of the Tulsa Section, composed of M. M. Valerius, Jon A. Udden, Charles T. Kirk, L. L. Hutchinson, Alf. G. Heggem.

The annual meeting of the Tulsa Section was held on Jan. 27, 1922. Officers and members of executive committee were elected for the current year, as follows: chairman, H. B. Goodrich, Tulsa, Okla.; vice-chairmen, J. A. Udden, Austin, Tex.; Wallace E. Pratt, Houston, Tex., Sidney Powers, Tulsa, Okla.; secretary-treasurer, R. S. McFarland, Tulsa, Okla.; executive committee, Alf. G. Heggem, Tulsa, Okla.; W. R. Hamilton, Tulsa, Okla., Alexander Deussen, Houston, Tex., Charles H. Taylor, Oklahoma City, Okla.

---

## Silver Discussed by Southern California Section

THE Southern California Section held a meeting on Jan. 13, with 65 members present. Walter Schmidt, acting chairman, presided. Before taking up the technical program of the evening, a short business session was held, the matter of principal interest being the report on the Bureau of Mines Bill by a committee composed of Messrs. Horace V. Winchell, chairman, Ralph Arnold and Nelson Nevius. This committee was appointed to consider and report on the proposed new Federal Mining Law as introduced by the Honorable Samuel S. Arentz (H R 7736). The reading of this report was followed by a general discussion by the members, and by resolution of the section, the majority report was approved.

Digitized by Google

The committee took up particularly the three fundamental changes proposed in the mining law as follows: First, to abolish the existing Apex Law and substitute therefor vertical bounding planes. This principle had the unanimous, earnest endorsement of the committee. Second, the new law would eliminate the proposed requirements of a mineral discovery as a pre-requisite to location. This principle, also, had the unanimous earnest endorsement of the committee. Third, that section of the law requiring the location of square claims of 40 acres each laid out on cardinal lines was advocated by two members of the committee and opposed by the third.

There being no further business, Horace V. Winchell was introduced by the chairman as the first speaker of the evening, his subject being "Silver, the Genesis and Occurrence of its Ores and Various Types of Silver Deposits." Mr. Winchell opened his remarks with a brief history of the Pittman Act and then described various types of silver deposits which had come under his observation. Rush T. Sill followed with some very interesting notes on silver and its ores.

## Oregon Section Favors Revision of Mining Laws

AT ITS annual meeting, held at Corvallis, Jan. 21, the Oregon Section discussed the report of the committee that had been appointed by the Section to consider H. R. 7736 Bill to Revise the Mining Code of the United States of America. W. B. Dennis, chairman of the committee, Mr. Newton and Mr. Swartley made addresses on the principal features of the bill. The following resolution presented by W. H. Woodward was carried as amended:

The Oregon Section of the A. I. M. E. is in favor of revising and codifying the present mining laws of the United States and is in accord with the principles of H.R. 7736 and the abolishment of the apex law and extralateral rights, but we wish to call attention to the following objections (Summarized here):

Provision should be made for acquiring mineral rights on withdrawals of public land under necessary regulations.

The location and holding of mining claims on which no discovery has been made should not be authorized on the same terms with claims having a discovery.

Verification of discovery should not be entrusted to deputy mineral surveyors or other officers except under restrictions.

The provision that one discovery shall be sufficient for 160 acres unduly restricts opportunities.

The provision requiring patent within seven years will work hardship on the poor prospector.

The form of location notice should be uniform in all states.

Provision should be made for easement for right of way for tunnels to reach mineral deposits or for drainage purposes from without the claims.

Provision should be made for recording proof of labor and this record should be compulsory.

The Section believes that the provision for claims to be located by legal subdivisions or on cardinal lines is inadvisable.

Previous to the discussion of the mining code, H. M. Parks was reëlected chairman, and P. R. Hines was elected secretary-treasurer.

The Section will hold an informal luncheon meeting at the Chamber of Commerce on the first Thursday of each month.

## New Local Section Formed at Charleston, West Virginia

THE Charleston Section of the American Institute of Mining and Metallurgical Engineers, to take in the mining region of southern West Virginia and northeastern Kentucky, was formally organized on Feb. 14. The following account of the opening sessions is taken in part from the *Charleston Daily Mail* and in part from a letter from one of the members.

J. K. Anderson was elected president, W. J. Priestley, vice president, and C. E. Krebs, secretary-treasurer. The officers were elected at the close of the afternoon meeting, at which several interesting technical papers were presented. E. F. Ketter, engineer of the U. S. Coal & Coke Co., spoke on Dry Cleaning Coal Mills; W. J. Priestley, superintendent of steel making at the U. S. Armor Plant, gave a paper on Latest Achievements in the Manufacture of Steel.

On the evening of Feb. 14, a banquet was held. Carl Scholz officiated as toastmaster and there were talks by Edwin Ludlow, president of the Institute; Arthur Thacher, of St. Louis; J. G. Bradley, of Dundon, W. Va., president of the national coal association; Phil M. Conley, in charge of the department of Americanization and thrift for school children, state department of education, Charleston, and others. The entertainment following the banquet was concluded with an exhibition of motion pictures of industrial activities in West Virginia, especially around Charleston.

President Ludlow said that he believes that the salvation of the mining industry rests on standardization of production and better preparation as the remedy for the customary overproduction. He advocated five-year contracts between producers and consumers as the best way of avoiding strikes and contentions with labor.

The address of Mr. Bradley was devoted more particularly to the problems of producing and marketing bituminous coal. He advocated greater efficiency in operation of mines and employment of labor.

Mr. Thacher's talk began with reminiscences, praise of progress made toward higher civilization and predictions of greater achievement to come, but toward the close of his address he gave his hearers the benefit of a fund of information gained from his long practical experience as an engineer in both coal and metals mining. He advocated closer human relations between employer and employee, an honest day's work for an

Digitized by Google

honest day's pay, and said that it had been his observation that a cheap wage means cheap work. He believes unionism for labor is founded on a wrong principle, will prove a failure and will be superseded by something better. "Not even a Sunday school picnic can be run with everybody taking a hand in the managing," he said, "it takes committees and representatives to get results."

Mr. Sumner, of the West Virginia Y. M. C. A., gave an account of the work his association is doing in the state.

On Feb. 15, the party visited the Owens Bottle Works at Kanawha City and witnessed the manufacture of bottles, an industry that is interesting to mining engineers because all the materials come from the mines in the vicinity. In the afternoon, the party visited the Naval Ordnance plant at South Charleston, under the guidance of Mr. Priestley.

## Affiliated Student Societies

**University of Oklahoma.**—The Pick and Hammer Club has an average attendance of 75 at its meetings. The officers are Earnest Word, president; Paul C. Teas, vice-president; Bess U. Mills, secretary-treasurer.

**Iowa State College.**—The Student Branch of the A. I. M. E. has officers as follows: Edward Thayer, president; Robert L. Wright, vice-president; Claude G. Grimm, secretary. The work of the society is being carried on with much enthusiasm and the meetings are well attended.

**University of Wisconsin.**—The Mining Club holds a meeting once a month, at which dinner is served and addresses are made on subjects of interest to the mining fraternity. The officers are W. F. Uhlig, president; A. M. Hill, vice-president; N. H. McKay, secretary-treasurer; M. M. Gorrow, mucker; D. M. Matheson, assistant mucker; E. W. Jones, publicity.

**Sheffield Scientific School, Yale University.**—The Mining Society has changed its name to Mining and Metallurgical Society. When the society was reorganized in January, the following officers were elected: chairman, W. K. Ziegfeld, Jr.; vice-chairman, F. W. Gledhill; secretary, H. D. Ruhm, Jr.; treasurer, W. R. Weaver.

**Lawrence College.**—The Geological Engineers Club recently arranged a meeting at which films on oil development were shown before a large community audience. The officers for the first semester of this year were Lloyd Wright, president; John Ockerman, secretary-treasurer. For the second semester, the president is Carroll A. Phillips, the vice-president is Carroll R. Rushton, and the secretary- treasurer is Homer M. Hunt.

**Case School of Applied Science.**—Every student taking the mining or metallurgical course, by tradition, must be initiated into the Pick and Shovel Club at the beginning of his sophomore year. Whenever possible, the members of the club attend the meetings of the Ohio Section and of the Steel Treaters Society. The officers are as follows: president, H. F. Roberts; vice-president, F. A. Lewis; secretary, I. E. Seith; treasurer, C. H. Hale; sergeant at arms, C. R. Brown.

## Woman's Auxiliary

THE regular monthly meeting of the General Council of the W. A. A. I. M. E. was held at the Engineering Societies Building, New York, Thursday, Feb. 2. Nine members were present, with Mrs. Philip Wiseman, of Los Angeles, as guest.

The Northern California section held a meeting on Jan. 27, at the Engineer's Club in San Francisco. The officers of this section are Mrs. Edmund Jüssen, chairman, Mrs. W. G. Morley, treasurer, and Mrs. Oliver C. Ralston, secretary.

This group of women is interested in finding a candidate for the Columbia University scholarship and for this purpose has enlisted the services of Dean Probert, of the University of California, and of Theodore Hoover, of Leland Stanford University.

The meetings of this section will be held on the fourth Wednesday of each month. Mrs. Sidney J. Jennings is acting proxy.

Mrs. Philip Wiseman, chairman of the Southern California section, read a letter from Mrs. W. F. Staunton, treasurer of that section, reporting its financial condition and expressing local views as to the best methods for the collecting of dues. On Jan. 3rd, this section held a luncheon at the Ambassador Hotel in Los Angeles, with 31 members present, during which Mrs. H. V. Winchell gave an interesting and thrilling talk on her experiences in Russia.

The Denver section reported having cast a unanimous vote for the revised constitution. This section is also in search of a candidate for the Columbia scholarship.

The Butte section also reported approval of the revised constitution and by-laws.

At its meeting on Jan. 17, the Utah section discussed the new constitution and by-laws. It did not express its approval of Article 8, Section 4, referring to the collection of dues. Mrs. Prosser was named proxy for this section for the ensuing year. Utah is also looking for a suitable candidate for the Columbia scholarship. There are 18 or 20 members at each of the monthly meetings. They collect and donate funds to various local charities.

The monthly luncheon of the New York Section was held at the Wiley's on Wednesday, Jan. 25, 1922. There were 68 present. Mrs. Mayer read a report in regard to the finding of quarters for the proposed club house and also presented an estimate of the cost of maintenance.

Digitized by Google

Mrs. Taylor read a report from Mrs. Mulliken of the Washington section in regard to sending books and presents to mining camps, then introduced the speaker of the day, Miss Elizabeth Leighton Lee of the School of Horticulture for Women at Ambler, Pa. Miss Lee explained the scope of the School of Horticulture and told of the opportunities offered to women in this field. She feels that gardening and the care of animals are most appropriate vocations for women because of their maternal instinct and their instinct for cleanliness. Questions from the members followed Miss Lee's talk.

Mrs. Jennings, chairman of the Educational Fund Committee, advises that she has received very satisfactory reports from the University of California respecting the work of James Christie, who is the recipient of the Woman's Auxiliary scholarship for the present year.

Mrs. Hardinge reported that she had received a generous donation of books from Mrs. Harold Banks to be sent to Payson, Arizona.

The secretary was instructed to write to the chairman of the Anaconda and Butte sections, expressing to them the delight of the General Council upon learning of the reopening of the mines and mills of those districts.

In closing, a rising vote of thanks was given Mrs. Dwight for her untiring energy in working for the good of the Auxiliary for the past two years and for her unfailing courtesy under all circumstances.

# Increase of Membership Department

**Total membership as of Feb. 11, 1922, is 10,243**

APPLICATIONS FOR MEMBERSHIP.—The Institute desires to extend its privileges to every person to whom it can be of service. On the other hand, it is not desirable that persons should be admitted to membership in classes for which they are not qualified. Members of the Institute can be of great service if they will make a practice of glancing through the list of applicants and promptly notifying the Committee on Membership, or the Secretary of the Institute, of any person whom they think should not be classified in accordance with the list given.

The following persons have been proposed during the period Jan. 20 to Feb. 18, 1922, for election as members of the Institute. Their names are published for the information of Members and Associates, from whom the Committee on Membership earnestly invites confidential communications, favorable or unfavorable, concerning these candidates. A sufficient period (varying in the discretion of the Committee, according to the residence of the candidate) will be allowed for the reception of such communications, before any action upon these names by the Committee. After the lapse of this period, the Committee will recommend action by the Board of Directors, which has the power of final election.

## Candidates for Membership

Members

**1—Laurence W. Bevan,** Kingston, Pa.
Present position—1917 to date: Assistant General Manager, Hazard Mfg. Co., Wilkes-Barre, Pa.
Proposers: H. H. Ashler, R. V. Norris, E. S. Moore.

**2—William Whipple Copp,** Taft, Cal.
Present position: Petroleum Engineer, State Mining Bureau.
Proposers: S. K. Dahl, M. A. Newman, Robert B. Moran.

**3—Albert J. Fleming,** Scranton, Pa.
Present position—1915 to date: Vice President, J. R. Fleming and Sons, Mine Car Equipment.
Proposers: E. H. Leaning, R. H. Buchanan, Eli T. Conner.

**4—Kumao Fuwa,** Taganagun, Fukuokaken, Japan.
Present position—1905 to date: Chief Engineer and Superintendent, Tagawa Colliery.
Proposers: Takuma Dan, Tamaki Makita, Jokichi Fujioka.

**5—Harry Samuel Gay,** Mount Gay, W. Va.
Present position—1913 to date: General Superintendent of Mines, The Gay Coal and Coke Co.
Proposers: Howard Eckfeldt, Howard N. Eavenson, H. S. Drinker.

**6—Lewis Sniger Gillette,** Natchez, Miss.
Present position—1920 to date: President, Plymouth Investment Co., President, L. S. Gillette Co., Vice-President, U. S. Chamber of Commerce and Chairman of its building.
Proposers: Herbert Hoover, John E. Hodge, Horace V. Winchell.

**7—George Perry Henderson,** Mayer, Ariz.
Present position—1920 to date: Surveyor, Assayer and Office Chief, Swastika Silver and Copper Co.
Proposers: Frank W. Giroux, John C. Greenway, W. V. DeCamp.

**8—James Thomas Higgins,** Paint Cliff, Ky.
Present position—1921 to date: Superintendent, Paint Cliff Mines Co.
Proposers: Ivor Livingston, Walter B. Miller, W. H. Noel.

**9—Jess Charles Johnson,** Seattle, Wash.
Present position—1920 to date: Consulting Mining Engineer.
Proposers: Paul Billingsley, Harry Townsend, Milnor Roberts.

**10—Kinji Kawai,** Sorachi, Hokkaido, Japan.
Present position: Mechanical Engineer, Sunagawa Colliery, Mitsui Min. Co.
Proposers: Takuma Dan, Tamaki Makita, Kojiro Nishimura.

**11—Saburo Kawashima,** Sunagawa, Sorachigun, Hokkaido, Japan.
Present position—1920 to date: Manager of Mitsui Sunagawa Colliery.
Proposers: Takuma Dan, Tamaki Makita, Kojiro Nishimura.

**12—Edwin Williams Klumple,** New York, N. Y.
Present position—1921 to date: Vice President, Merring, Hicks and Co., Williamson, W. Va.
Proposers: Alan R. Blackburn, Samuel Melitzer, R. M. Peterson.

**13—Thomas Cooper Linderfelt,** Bartlesville, Okla.
Present position—1921 to date: Chief Geologist, Rood Oil Corpn.
Proposers: H. T. Beckwith, Alexander W. McCoy, A. L. Beekly.

Digitized by Google

**14—Henry William Lohman,** Bellerose, L. I., N. Y.
Present position—1918 to date: Vice President and Treasurer, United Zinc Smelting Corp., New York, N. Y.
Proposers: Edwin O. Holter, B. B. Gottsberger, R. T. Cornell.

**15—Edward William Macleod-Elliott,** Likasi, Union Miniere, Katanga, Congo Belge.
Present position—1920 to date: Mine Captain and Acting Assistant Manager.
Proposers: A. E. Wheeler, F. W. Snow, Thomas S. Carnahan.

**16—Charles Williams Maxwell,** Marigold, Cal.
Present position—1916 to date: Amalgamator, Surveyor, Assistant to Manager, Marysville Dredging Co.
Proposers: Roy H. Elliott, Gerald H. Hutton, Edwin Higgins.

**17—Nagao Nomura,** Sunagawamura, Sorachi, Hokkaido, Japan.
Present position—1920 to date: Mining Engineer at Mitsui Sunagawa Colliery.
Proposers: Takuma Dan, Tamaki Makita, Jokichi Fujioka.

**18—Kiyoshi Oda,** Ohmuta, Chikugo, Japan.
Present position—1921 to date: Engineer and Superintendent, Mitsui Miike Metal Refinery, Mitsui Mining Co., Ltd., Tokyo, Japan.
Proposers: Takuma Dan, Tamaki Makita, Kojiro Nishimura.

**19—B. Marvel O'Harra,** Rolla, Mo.
Present position—1921 to date: Associate Metallurgist, U. S. Bureau of Mines.
Proposers: Charles Y. Clayton, Charles H. Fulton, Dorsey A. Lyon.

**20—Stanley Francis O'Leary,** Kingman, Ariz.
Present position—1921 to date: Manager, William C. Fastnow and Co. and Manager, Katherine Victor M. Co. and Manager, Oatman-Standard Mines Co.
Proposers: W. B. Phelps, Richard G. Place, S. Ford Eaton.

**21—Tokima Okitsu,** Sorachigun, Hokkaido, Japan.
Present position—1919 to date: Mining Engineer, Mitsui Sunagawa Colliery.
Proposers: Takuma Dan, Tamaki Makita, Kojiro Nishimura.

**22—Herman Phillippi,** Scheveningen, Holland.
Present position: Director of the Eerste Nederlandsch Indishe Hoogoven Maatschappy.
Proposers: L. Duparc, Max Reinhard, J. T. Erb.

**23—Leonard Cooke Phillips,** Durango, Mexico.
Present position: President and General Manager, Cia Minera Occidental, S. A.
Proposers: George H. Packard, J. A. Udden, E. L. Porch.

**24—Clifford Miller Roehrig,** Huntington, W. Va.
Present position—1921 to date: Consulting Engineer in business for myself.
Proposers: Newell G. Alford, Howard N. Eavenson, W. H. Cunningham.

**25—Yoshima Sayeki,** Tokyo, Japan.
Present position—1895 to date: Mining Engineer, Mitsui Mining Company, Ltd.
Proposers: Takuma Dan, Tamaki Makita, Iokichi Fujioka.

**26—Theodore Aloysius Schmidt,** Morris Run, Tioga County, Pa.
Present position—1912 to date: Mining Engineer, Morris Run Coal Mining Co.
Proposers: Theodore S. Barber, Douglas Bunting, Charles G. Morgan.

**27—Tsutomu Shibata,** Tokyo, Japan.
Present position—1915 to date: Mining and Metallurgical Engineer, Mitsui and Co.
Proposers: Takuma Dan, Tamaki Makita, Jokichi Fujioka.

**28—Mataroku Takagishi,** Sunagawamura, Sorachigun, Hokkaido, Japan.
Present position—1917 to date: Mining Engineer, Mitsui Sunagawa Colliery, Sorachigun.
Proposers: Takuma Dan, Tamaki Makita, Jokichi Fujioka.

**29—Toshiro Tsukamoto,** Ohmuta, Fukuokaken, Japan.
Present position—1921 to date: Metallurgical Engineer, Mitsui Miike Metal Refinery of the Mitsui Mining Co., Ltd., Tokyo, Japan.
Proposers: Takuma Dan, Tamaki Makita, Kojiro Nishimura.

**30—Lewis A. Turnbull,** St. Louis, Mo.
Present position: Assistant to Chief Engineer, Western Coal and Mining Co.
Proposers: C. R. Forbes, H. A. Buehler, A. W. Dickinson.

**31—Frank K. Weaver,** Olcott, W. Va.
Present position—1921 to date: Vice President and General Manager, Kanawha Black Band Coal Co.
Proposers: Charles E. Krebs, J. M. Clark, Ernest M. Merrill.

**32—Gosanji Yasnaga,** Kawakami, Karafuto, Japan.
Present position—1920 to date: Manager of the Mitsui Kawakami Colliery.
Proposers: Takuma Dan, Tamaki Makita, Jokichi Fukioka.

Associates

**33—Waldo Peck Adams,** Elizabeth, N. J.
Present position:
Proposers: Leonard Waldo, Philip W. Henry, W. N. Best.

**34—Francis Herbert Blatch,** Hazleton, Pa.
Present position: Assistant General Manager, Wilmot Engineering Co.
Proposers: George R. Wood, Herbert D. Kynor, H. W. Montz, T. E. Snyder.

**35—Herbert G. Buel,** Allentown, Pa.
Present position—1921 to date: Sales Manager, Tilghman H. Moyer Co.
Proposers: A. B. Jessup, C. A. Garner, Paul Sterling.

**36—Adolph Oliver Dovre,** Maracaibo, Venezuela, S. A.
Present position: Chief Geologist, Venezuelan Sun, Ltd.
Proposers: J. Whitney Lewis, Fred H. Kay, H. J. Wasson.

**37—Solomon Gilbert Drushel,** Edna, Texas.
Present position—1907 to date: President, Jackson County State Bank.
Proposers: E. G. Woodruff, J. A. Udden, D'Arcy M. Cashin.

**38—Homer Moore Eagles,** Brooklyn, N. Y.
Present position—1920 to date: Petroleum Engineer, James L. Darnell, Arthur Eaton, Engrs., New York, N. Y.
Proposers: Arthur Eaton, Ellis H. Phillips, D. S. Tovey.

**39—Walter Essington Eisenburg,** Los Angeles, Cal.
Present position: Student, University of Nevada School of Mines, Reno, Nev.
Proposers: J. C. Jones, F. C. Lincoln, Henry M. Rives.

**40—Le Roy Fowler Knight,** Scranton, Pa.
Present position: Engineer with Stevenson and Knight.
Proposers: M. S. Knight, George E. Stevenson, Cadwallader Evans, Jr.

**41—Donald Kenneth Mackay,** Tampico, Mexico.
Present position—1921 to date: Geologist, International Petroleum Co., Tobasco, Chiapas Field.
Proposers: W. Armstrong Price, Rex Townsend, A. W. Abraham.

**42—Laurence Stillman Morrison,** Redlands, Cal.
Present position—1921 to date: Geological Assistant to Mr. J. R. Finlay, New Mexican Mine Appraisal.
Proposers: J. T. Matson, J. R. Finlay, Cony T. Brown.

**43—Saburo Sugiyama,** Omuta, Fukuoka-ken, Japan.
Present position—1919 to date: Metallurgical Engineer, Mitsui Mining Co., Ltd., Mitsui Miike Metal Refinery, Tokyo, Japan.
Proposers: Takuma Dan, Tamaki Makita, Kojiro Nishimura.

**44—Alan Porter Sullivan,** St. Marys, Pa.
Present position—1920 to date: Research Engineer in charge of Research Laboratory, Stackpole Carbon Co.
Proposers: Frank J. Tone, R. L. Baldwin, F. A. Lidbury.

**45—Howard Volney Tygrett,** Bowling Green, Ky.
Present position—1921 to date: Geologist, Atlantic Oil Producing Co.
Proposers: Roswell H. Johnson, L. G. Huntley, R. E. Somers.

Junior Associates

**46—Eugene Randolph Aaron,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, J. J. Lillie, T. M. VanTuyl.

**47—Irving Wyland Alcorn,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: Charles Y. Clayton, M. H. Thornberry, Thomas M. Bains, Jr.

**48—Sherwood Buckstaff,** Madison, Wis.
Student, University of Wisconsin.
Proposers: E. R. Shorey, Richard S. McCaffery, A. N. Winchell.

**49—William H. Brugmann,** Bethlehem, Pa.
Student, Lehigh University.
Proposers: G. A. Roush, Allison Butts, H. B. Pulsifer.

**50—Beryl Elwood Charles,** Salina, Kansas.
Student, Missouri School of Mines, Rolla, Mo.
Proposers: C. R. Forbes, J. R. Guiteras, C. L. Dake.

**51—Dewitt Clinton Deringer, Jr.,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, Victor C. Alderson, F. D. Aller.

Digitized by Google

**52—Robert Marvin Edwards,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, Victor C. Alderson, Lester S. Grant.

**53—George Newlin Ewing,** Philadelphia, Pa.
Student, Lehigh University, So. Bethlehem, Pa.
Proposers: G. A. Roush, Benjamin L. Miller, Howard Eckfeldt.

**54—Mervin Obert Flom,** Madison, Wis.
Graduate Student, University of Wisconsin.
Proposers: Richard S. McCaffery, E. R. Shorey, A. N. Winchell.

**55—Muir Luken Frey,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: M. H. Thornberry, Charles Y. Clayton, Charles H. Fulton.

**56—Joseph Haskin,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, I. A. Palmer, Victor C. Alderson.

**57—James Stewart Huston,** South Bethlehem, Pa.
Student, Lehigh University.
Proposers: Allison Butts, G. A. Roush, Benjamin L. Miller.

**58—Norbert William Hyland,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, J. J. Lillie, Victor C. Alderson.

**59—Charles L. Kofke,** Philadelphia, Pa.
Student, Lehigh University, So. Bethlehem, Pa.
Proposers: G. A. Roush, Howard Eckfeldt, Benjamin L. Miller.

**60—Roland Joseph Lapee,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: Charles Y. Clayton, Thomas M. Bains, Jr., C. R. Forbes.

**61—Lawrence Litchfield, Jr.,** Cambridge, Mass.
Harvard Engineering School.
Proposers: H. L. Smyth, L. C. Graton, George S. Raymer.

**62—Edward Rutledge Loundes, Jr.,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, J. J. Lillie, T. M. Van Tuyl.

**63—Thomas Seward Lovering,** Minneapolis, Minn.
Student, University of Minnesota.
Proposers: W. R. Appleby, W. H. Parker, Peter Christianson.

**64—Maurice Courtney McClellan,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: Charles Y. Clayton, C. R. Forbes, C. L. Dake.

**65—William Christopher McCulloch,** Seattle, Wash.
Graduate Student, University of Washington.
Proposers: Joseph Daniels, Milnor Roberts, C. R. Corey.

**66—Edward G. Maddock,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, I. A. Palmer, Victor C. Alderson.

**67—Guy Verdier Martin,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: Charles Y. Clayton, Thomas M. Bains, Jr., M. H. Thornberry.

**68—Carl E. Millikan,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: Charles Y. Clayton, C. L. Dake, C. R. Forbes.

**69—Lute James Parkinson,** Golden, Colo.
1919–1922, Colorado School of Mines.
Proposers: J. C. Roberts, Victor C. Alderson, Lester S. Grant.

**70—Edwin Noel Pennebaker,** Berkeley, Cal.
University of California.
Proposers: Frank H. Probert, W. S. Morley, Oliver C. Ralston.

**71—Carleton Richardson,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, Victor C. Alderson, F. D. Aller.

**72—Elbert F. Robinson,** Berkeley, Cal.
Student, University of California.
Proposers: Frank H. Probert, Walter S. Morley, Lester C. Uren.

**73—Ambrose Chockley Rucker,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: C. R. Forbes, J. R. Suiteras, C. L. Dake.

**74—Christopher Winfree Ryan,** Golden. Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, T. M. VanTuyl, Victor C. Alderson.

**75—Paul Maxwell Sheriger,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, J. J. Lillie, Victor C. Alderson.

**76—John H. Stoll,** Bethlehem, Pa.
Student, Lehigh University.
Proposers: G. A. Roush, Howard Eckfeldt, H. B. Pulsifer.

**77—James Taylor,** Socorro, N. M.
Student, New Mexico State School of Mines.
Proposers: T. W. Quayle, W. G. Ramlow, E. H. Wells.

**78—John Peter Withers, Jr.,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, J. J. Lillie, Victor C. Alderson.

Change of Status—Associate to Member

**79—Daniel Boyd,** Phillipsdale, R. I.
Present position—1921 to date: Metallurgical Research with American Electrical Works.
Proposers: C. W. Drury, Stanley N. Graham, G. J. MacKay.

Change of Status—Junior Associate to Member

**80—Edgar Kraus,** Houston, Tex.
Present position—1921 to date: Geologist, Gulf Coast District, Atlantic Oil Producing Co.
Proposers: J. J. Galloway, W. G. Matteson, R. M. Raymond, D. M. Cashin, Donald C. Barton.

**81—Kenneth Murchison Sully,** Gibson, N. M.
Present position—1921 to date: Engineering and Construction work, Gallup American Coal Co.
Proposers: H. G. S. Anderson, John M. Sully, Horace Moses.

Change of Status—Junior Associate to Associate

**82—Eric Roy Emmerson,** Port Arthur, Ont., Canada.
Present position—1919 to date: Unemployed. Examining claims, prospecting, etc., when conditions and health permits.
Proposers: H. E. T. Haultain, George A. Guess, Frederick C. Dyer.

**83—Edward Meagher,** Brooklyn, N. Y.
Present position—1921 to date: Sales Department, Texas Gulf Sulphur Co.
Proposers: R. M. Raymond, Walter H. Aldridge, H. R. Wemple.

**84—Julien M. J. O. Raick,** Liege, Belgium.
Present position—Mining Engineer.
Proposers: Herbert Hoover, W. F. Dietrich, Theodore J. Hoover, W. H. Shockley.

## Do You Know Where These Men Are?

| Name | Last Address of Record from which Mail Has Been Returned |
|---|---|
| Abadie, Emile | Blue Mountain Gold Mine, Woody, Cal. |
| Alsdorf, F. C. | Inn Hotel, Shreveport, La. |
| Appleton, John R. | Colorado School of Mines, Golden, Colo. |
| Armstrong, Clifton T. | Pachuca, Hidalgo, Mexico. |
| Block, James A. | Resident Engr., Thacker Fuel Co., New Thacker, W. Va. |
| Blow, John J. | 404 High Holborn, London, W. C., England. |
| Bradley, D. H., Jr. | Box 93, Prescott, Ariz. |
| Carns, Foss D. | Arizona Binghamton Copper Co., Stoddard, Ariz. |
| Chang, Ko Chi | Student, Carnegie Inst.of Tech., Pittsburgh, Pa. |

# Engineering Societies Library

HARRISON W. CRAVER, Director

The Engineering Societies Library, on the 13th floor of the Engineering Societies Building, 29 West 39th St., New York, contains approximately 150,000 volumes of engineering literature. It is open on week days, excepting holidays, from 9 a.m. to 10 p.m.

The Library offers, upon payment for the extra work required, to supply photoprints or translations of articles, make searches for information, prepare lists of references and suggest books on engineering subjects. The cost of searching is $2 an hour. Translations cost $6 and upwards per thousand words. Typewritten copies, $1 a thousand words. Photoprints, 11 by 14 in., cost $0.25.

In cases where the Library contains two copies of a book, one may be borrowed by any member. Transportation costs must be paid by the borrower.

The Library is at the service of every member. Those who cannot visit it may order searches, translations, copies, etc., by mail.

Address correspondence to the Director, Harrison W. Craver, 29 West 39th St., New York.

## Book Notices

**Architects' and Builders' Handbook.** By Frank E. Kidder. Seventeenth edition. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 1907 pp., illus., tables, 7 × 4 in., fabrikoid, $7.

Two new chapters, on Specifications for the Steelwork of Buildings, and on Domical and Vaulted Structures, have been prepared for this edition. The chapters on Fireproofing of Buildings and on Reinforced-concrete Construction and the sections on Heating and Ventilation and on Chimney Construction have been rewritten. The whole text has been revised and numerous new articles have been inserted. The book contains information on every subject, except design, likely to come before an architect, structural engineer, draftsman or builder.

**Atomic Theories.** By F. H. Loring. N. Y., E. P. Dutton and Co., 1921. 218 pp., illus., 9 × 6 in., cloth, $5.

Leading facts and theories relating to the atom, particularly the new ones which have not yet been treated at any length in textbooks. The book covers a wide range of subjects, including the quantum theory, Sir J. J. Thomson's recent views on mass, matter and radiation, the Bohr theory, the octet theory, isotopes, the Brownian movement, ionisation, potentials, solar phenomena, etc.

**Construction, Cost Keeping and Management.** By Halbert Powers Gillette and Richard T. Dana. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1922. 572 pp., forms, 8 × 5 in., cloth, $5.

Prepared in response to requests for a second edition of "Cost Keeping and Management Engineering." Nearly all the original material, supplemented by that developed in the last twelve years. Explains rules of management and suitable methods of cost keeping adapted to engineering construction.

**Descriptive Geometry.** By George Young and H. E. Baxter. N. Y., The Macmillan Co., 1921. 310 pp., diagrs., 8 × 5 in., cloth, $3.25.

Believing that the chief value of descriptive geometry lies in its imaginative quality, these authors present it so as to develop the imagination. The treatment has been kept purely abstract, but introductory matter showing the relation of the principles under discussion to structural work is provided, and exercises to show the application of the abstract ideas to concrete, practical problems are included.

**Design of Steel-Mill Buildings and Calculation of Stresses in Framed Structures.** By Milo S. Ketchum. Fourth edition, rewritten. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 632 pp., illus., diagrs., 9 × 6 in., fabrikoid, $6.

A textbook in structural engineering and also a book of reference for engineers. Part 1 covers the calculation of the stresses in simple beams, trusses, portals, the transverse bent and the three-hinged arch. Part 2 covers the calculation of the deflections of structures, the stresses in statically indeterminate girders, trusses and frames, and secondary stresses in trusses. Part 3 covers the design of steel frame buildings for mines, mills, smelters and other industrial plants. The appendix is a complete specification for steel-frame mill buildings.

**Edge Moor Water Tube Boiler.** Edge Moor, Del., Edge Moor Iron Co., 1922. 153 pp., illus., 9 × 6 in., cloth.

Contains data on oil firing, waste heat recovery, properties of fuels, water purification, steam tables, etc., in addition to technical information concerning the Edge Moor boiler.

**Die Eisenkonstruktionen.** By L. Geusen. Dritte, verbesserte auflage. Berlin, Julius Springer, 1921. 282 pp., diagrs., tables, 11 × 8 in., cloth, 384 Mk.

Textbook for students of structural engineering. Section 1 gives the principles of steel construction; Section 2 deals with steel buildings and Section 3 with bridges. The text is concise and illustrated by numerous drawings. An appendix contains the necessary tables of the properties of structural shapes.

**Elements of Fractional Distillation.**—By Clark Shove Robinson. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1922. (International chemical series.) 205 pp., tables, diagrs., 8 × 6 in., cloth, $2.50.

The first portion of this book treats of fractional distillation from the qualitative viewpoint of the phase rule; the second discusses some quantitative aspects from the engineering point of view; and the third section treats of the design of distilling apparatus. Part four gives examples of modern apparatus for distilling ammonia, benzolized wash oils and alcohols. An appendix of useful tables is included.

Digitized by Google

**Essentials of Industrial Costing.** By George S. Armstrong. N. Y., D. Appleton and Co., 1921. 297 pp., tables, forms, 9 × 6 in., cloth, $5.

This book is concerned solely with the principles and methods by which the cost of production may be determined. It is based upon an extended experience in many different industries and represents the author's mature views. It shows the purpose of costing, summarizes good practice and is a guide to the analysis necessary for the establishment of costing systems.

**Handbuch der Drahtlosen Telegraphie und Telephonie.** By Eugen Nesper. Berlin, Julius Springer, 1921. 2 vol., illus., diagrs., 10 × 7 in., cloth.

This book is apparently more extensive than any previous work on the subject. The theory of radio communication, its history, uses, measuring and detecting instruments, physical phenomena in quasi-stationary circuits, coupling, damping, radiating, technique and apparatus of high-frequency measurements, are described in Volume 1. Volume 2 describes typical radio stations for different purposes and their apparatus, the uses of radio communication in railroading and radio telephony. It also includes a valuable bibliography of the important books and articles. Good indexes are provided.

**Hydraulics and Its Applications.** By A. H. Gibson. New edition, revised and enlarged. N. Y., D. Van Nostrand Co., 1921. 813 pp., illus., diagrs., 9 × 6 in., cloth, $6.

This book gives a description of the physical properties of water, followed by a brief treatment of the fundamentals of hydrostatics. The science of hydraulics is then presented, first theoretically and then with regard to its application to the design of hydraulic machinery. The work is primarily for students, but may also be valuable to those actively engaged in the practice of hydraulic engineering.

**Industrial Fatigue and Efficiency.** By H. M. Vernon. Lond., George Routledge & Sons, Ltd.; N. Y., E. P. Dutton & Co., 1921. 264 pp., tables, 9 × 6 in., cloth, $5.

The author is an investigator for the Industrial Fatigue Research Board of Great Britain and presents a fairly complete account of our present knowledge concerning industrial fatigue and its influence on efficiency. The information given relates only to shop practice.

**Manual of Flotation Processes.** By Arthur F. Taggart. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 181 pp., diagrs., 9 × 6 in., cloth, $3.

Widespread understanding of the physical principles underlying flotation phenomena and of the diversity of flotation processes has been delayed, partly by the apparent complexity of the phenomena and the difficulties of investigation, in part by the attitude of corporations owning patents on flotation processes. It is the purpose of this book, in part, to counteract the further spread of false conceptions, by setting forth some of the facts that contradict them, in part to describe apparatus and methods of testing which will aid investigators in their researches; and finally to give some generalizations from mill practice, by means of which the investigator may translate laboratory results into commercial operations.

**Maschinenuntersuchungen und das Verhalten der Maschinen im Betriebe.** By A. Gramberg. Zweite, erweitete auflage. Berlin, J. Springer, 1921. (Maschinentechnisches versuchswesen, bd. 2.) 681 pp., illus., 9 × 6 in., cloth.

Volume two of the author's treatise on methods for testing machines, the first volume of which is devoted to measuring apparatus. This volume discusses methods of testing and the behavior of machines while running. The subjects treated include boiler tests, fuel tests, heat conductivity, steam turbines and reciprocating engines, exhaust steam utilization, internal combustion engines, pumping machinery, blowers, air compressors and refrigerating machines. A section is devoted to regulation and governing. An introductory section discusses the economic and legal aspects of tests.

**La Matière et l'Énergie Selon la Théorie de la Relativité et la Théorie des Quanta.** By Louis Rougier. Nouvelle édition, revue et augmentée. Paris, Gauthier-Villars et Cie, 1921. 112 pp., 10 × 7 in., paper, 9.50 fr.

This book calls attention to the most paradoxical and least discussed consequence of the principle of relativity, that which constitutes mass, weight and structure to energy. What we call matter thus becomes only a particular case of energy. The old duality of ponderable and imponderable makes way for that of the electro-magnetic field or *energy*, of which radiation and matter are simple modalities, and of the field of gravitation or *space* as defined by Einstein. Professor Rougier presents these theories in this work.

**Metallurgy of Zinc and Cadmium.** By H. O. Hofman. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1922. 341 pp., diagrs., tables, 9 × 6 in., cloth, $4.

This volume resembles the author's previous treatises on copper and lead in its general characteristics and, like them, is supplied with copious references to the literature. Includes recent advances in the metallurgy of zinc and cadmium, and discusses these from a chemical as well as a technical point of view.

**Motor Truck Transportation.**—By F. Van Z. Lane. N. Y., D. Van Nostrand Co., 1921. 153 pp., illus., 9 × 6 in., cloth, $2.

A practical presentation of the principles of truck operating cost; operating efficiency and cost records; operating cost laws; truck details, such as bodies, loading and unloading devices, trailers and semi-trailers, and tires; and the factors that determine the fields of economical operation. Gives no attention to design or manufacture.

# Employment Service Bureau

Notices for this column are not acknowledged by letter. Notices received before the 15th of the month will appear in the next issue.

Correspondence relating to replies to advertisements returned to the Employment Bureau will be held in the Bureau for one month.

Positions of the Bureau are on file in the offices of the member societies of the Federated American Engineering Societies and with secretaries of A. I. M. E. local sections.

## Engineers Available

**Mining Executive.**—Technical education and practical experience in developing and operating anthracite, bituminous, copper and gold properties. 28 years. Special service or official capacity. IM–1538.

**Mining and Metallurgical Engineer.**—Graduate. Experience as assayer, chief chemist, sampler, engineer, hydrometallurgy of copper, two years foreign exploration and development. Age 30. Single. Minimum salary $3000. On foreign work necessary traveling and living expenses in addition to salary. IM–1539.

**Mining Engineer.**—Twenty years practical experience in development and operation of anthracite and bituminous mines. IM–1540.

**Quarry and Open-cut Operator.**—Has made specialty of surface mining of large orebodies, big tonnages and low unit costs. College man, age 39, married. Eight years experience in the United States and seven in Mexico, in gold, silver-lead and copper properties, underground, surface operations, construction, efficiency and cost analysis. Speaks Spanish fluently. Available after Dec. 1, 1921. IM–1541.

Digitized by Google

**Recent Graduate.**—E. M. metal mining and geology. New York interview. IM–1542.

**Superintendent or Mining Engineer.**—Columbia graduate. Nine years superintending mines, chiefly coal; two years consulting mining engineer in coal field. Considerable construction experience. Practically and technically trained to manage operations or act as chief engineer. Age 35. Married. IM–1543.

**Mining Engineer.**—Design and construction of coal tipples, power plants and general machinery. Surveying, mapping and general coal-mine development. Experienced draftsman in all work. IM–1544.

**Engineer.**—Desires position as instructor or assistant in teaching mining engineering, coal mining or civil engineering subjects in college. Master of Science degree. Some teaching experience and over five years practical work. IM–1545.

**Engineer.**—Twelve years in construction design and executive management. Desires to locate west or south of Denver. Speaks Spanish. Experience includes bridges, reinforced concrete, buildings, hydraulics, hoisting, conveying, aerial tramways. Development, design and selection of equipment for plants handling copper ores a specialty. Familiar with leaching and smelting. Can select and supervise men and meet executives of other concerns with tact and success. IM–1546.

**Petroleum Geologist.**—Graduate. Experience in Mid-continent fields. Wishes position in United States. IM–1547.

**Metallurgical Engineer.**—Columbia graduate; successful research and operating experience in iron and steel and nonferrous alloys. IM–1548.

**Material Engineer.**—Technical graduate. Five years experience in specifying materials, drafting purchasing specifications, and general metallurgical work on the consuming end. One year as metallurgist in a steel plant. Position in purchasing as director of research, or along metallurgical lines. IM–1549.

**Manager or Superintendent.**—Construction or operation. Seventeen years surface and underground mining, and in concentration plants, principally non-metallics. Now developing and marketing raw materials. Position preferably in Southeastern States. Age 37. IM–1550.

**Chemical Engineer.**—Seven years as production superintendent in Chile. Experienced in leaching ore, treatment of slimes, filtration, etc. Thoroughly familiar with Spanish. IM–1551.

**Mine or Quarry Manager.**—Technical graduate, 10 years' experience in South America, United States, and India. Last 2½ years in charge of about 5000 labor in open cut mines in India. Age 33. Married. Speaks Spanish. IM–1552.

**Mine Manager or Assistant.**—Technical graduate. Postgraduate business course. Successful independent business experience. Five years in mining, geology, and milling. Age 29. Married. Speaks Spanish. Available 3 to 6 months notice. Present salary $6000. IM–1553.

## Positions Open

**Transmission Line Superintendent.**—Applicant must be conversant with practice in transmission lines 100,000-volt, three-phase, 50-cycle; must be capable of taking entire charge of transmission system of approximately 400 mi. of line; must be familiar with both construction and operating work; and must be capable of handling native help. Reply, stating age, experience, training, and salary desired. India. X–1292.

**Graduate Mechanical Engineer** experienced castings and structural iron, design for job and small quantity production. Design wet chemical and metallurgical plants, acid-proof work, able to meet engineers and inspire confidence. Handle draftsman efficiently, preferably some plant operating experience. Prefer single active man between 30–35 years, prepared to hustle hard to learn business. Accuracy and carefulness absolutely essential, business training desirable. New York. V–284.

**Mining or Metallurgical Engineers.**—To study fertilizer business from manufacturing end. Young men, preferably around 30, whom we could send around to various plants to check processes, economies, machinery installation, etc. and to study details of plant operations. Slight knowledge of Spanish woud be beneficial as we have two plants in Cuba. Give age, education and experience. Chicago, Ill. V–295.

**Engineer.**—To take charge of machine and iron foundry. Average of 20 to 30 tons per day, of general foundry castings; most of work averaging fair weight. We have one loam job, making cylinders for dryers used on paper machines, but very little other loam work. General line is paper-making machinery. V–296.

**Competent Mine Foreman.**—To take charge of small operation where work is being done underground with overhand stoping. Prefer young technical graduate, with at least two years practical experience underground. North Caroline. V–266.

**Mining Engineer.**—Experienced in extracting gold by the cyanide process. Must have good personality and be able to advertise and sell process. South Africa. V–268.

**Engineer.**—To run flotation plant treating 10,000 tons per month of cyanide tails pumped to mill. V–252.

**Engineer.**—To run main unit of mill, which is concentration and flotation plant treating 6000 tons per month low-grade silver ore. V–253.

**Geologist** with 5 years experience in oil geology. Knowledge of Spanish for work in tropics. V–247.

**Technical Graduate.**—Preferably mechanical, with four or more years of practical experience with boilers, engines and electrical equipment and two or more years experience in college teaching. Ability to write on technical subjects in popular style is absolutely essential. Give details regarding training, experience, references, and salary desired. V–248.

**Engineer** for advertising field. Prefer man who has had at least five years' business experience in metal-trade field. Must be able to take first-class photographs of machinery and machine-shop interiors. Duties would entail traveling more or less so he would also have to have some knowledge of repairing and driving of automobiles. Application by letter. V–180.

**Surgeon** for company in Chile. Single man preferred. V–272.

**Engineer.**—To take charge of management department of a real-estate office. Must have had actual experience in renting and operating high-class office building. New York City. V–303.

**Assayer** having considerable experience melting and assaying gold, silver and platinum. New York City. V–307.

**Mine Foreman** with bituminous coal mining experience. Scientific management experience also essential. V–355.

**Research Graduate Assistantships.**—For detailed information, write to The Director, Engineering Experiment Station, University of Illinois, Urbana, Ill.

---

**Union of Friends of the Mining Academy of Freiberg** was founded on Dec. 3, 1921. It purposes to support the Mining Academy in its problems of research and instruction, to assist students, and to form a permanent connection between the high school and its former students and associates. The chairman is Dr. Inge. K. Sorge, chairman of the Federal Union of German Industry; the office is at the rectorate of the Mining Academy. The society requests former students and friends to become members.

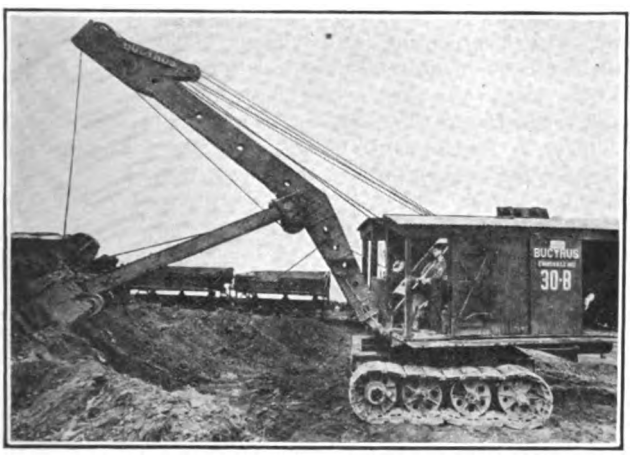
# Industrial News and Developments

Devoted to manufacturing and trade news of interest and value to the mining and metallurgical industry and invited from manufacturers and dealers. Scrutinized but not vouched for by the Institute.

## Gasoline Revolving Shovel

A SHOVEL operated by gasoline, with no engines, motors, shafts, chains or gears on the boom and yet with an actual digging power greater than a steam shovel of the same size, has been announced by the Bucyrus Company of South Milwaukee, Wis. This machine is known as the 30-B gasoline shovel.



BUCYRUS 30-B GASOLINE SHOVEL LOADING DUMP CARS.

For more than 10 years Bucyrus dragline excavators have been operated by gasoline engines, but the application of this power to the revolving shovel involved more difficult and intricate problems, chief among these being the efficient transmission of power to the thrust without excessive complication in design, and the obtaining of digging power commensurate with that of a steam machine of similar size. Both of these problems have been satisfactorily solved in this new shovel.

This shovel is simpler than a steam, electric or other type of gasoline shovel and has fewer parts to maintain and keep in order. It has all the well-known performance characteristics of a steam shovel, even to the shaking of the dipper to relieve it of sticky material. It will give 20 per cent. greater yardage per gallon of gasoline than an electric shovel of the same size, or than any other type of shovel whose power is derived from a gasoline engine. The shovel carries a 1-yd. dipper.

The gasoline engine with which this shovel is equipped was designed especially from specifications offered by the Bucyrus engineers. It is a four cylinder, slow-speed type and will develop 55 hp. at a speed of 400 r.p.m. It is entirely inclosed and thus dust proof.

A bulletin has recently been issued describing and illustrating this machine in detail, which may be obtained from the Bucyrus Company.

## Romance of Wire Rope

"OUTSPINNING the Spider" is the title of a small book by John Kimberly Mumford, published by R. L. Stillson Co., New York. For the most part it relates the growth of wire making as reflected in the growth of the John A. Roebling Sons Company.

The book is written in a popular vein, understandable to the layman, and is in no sense technical.

The first Roebling rope was finished in 1840. John Roebling had a vision of the part that wire rope was to play in the industrial development of the world and from the start realized the universal mission of twisted wire.

Wire cableways for hauling material over rivers and gorges soon ceased to be a novelty. Despite the opposition of engineers and others, by 1844 Roebling had not only perfected his theory of wire bridges, but in spite of criticism had built a wire bridge as an aqueduct for the Old Pennsylvania Canal, the basins of which were at Pittsburgh. This was followed by the construction of a wire bridge over the splashing and fuming waters of Niagara, the first of its kind to carry railroad traffic.

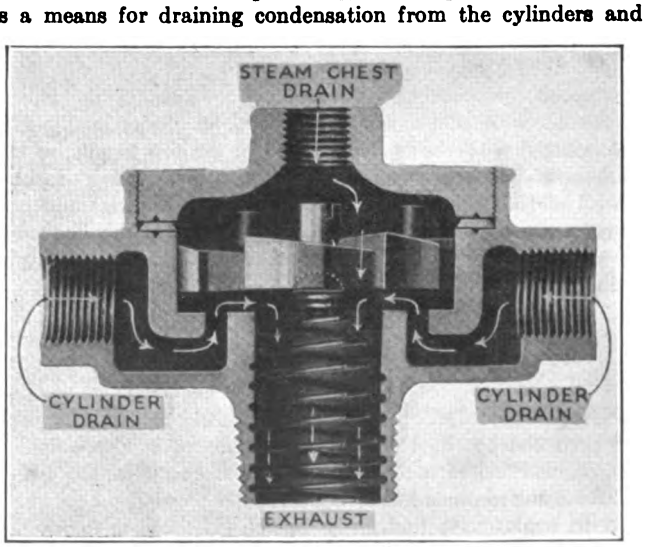
Speaking of this accomplishment, the author says: "All the world of that day knew, but most of it now has forgotten, how he (John Roebling) flew a kite across the gorge to get his first wire over and from that built up his cables. On March 16, 1855, the first train passed over it."

The summit of achievement in the building of bridges of wire came with the construction of the Brooklyn Bridge, considered the Eighth Wonder of the World. It was while occupied in this work that John Roebling sustained a slight injury that resulted in his death.

"Outspinning the Spider" relates in a vivid way the various processes used, the exacting care necessary and a few of the various uses to which wire rope is put.

## Automatic Drain and Relief Valve

THE Improved Diel-More Automatic Drain and Relief Valve is for use on all reciprocating, steam-operated equipment as a means for draining condensation from the cylinders and steam chest. It is entirely automatic in its operation; the relief feature takes care of any over-load pressure in either end of the cylinder while the engine is operating.



DIEL-MORE AUTOMATIC DRAIN AND RELIEF VALVE.

Digitized by Google

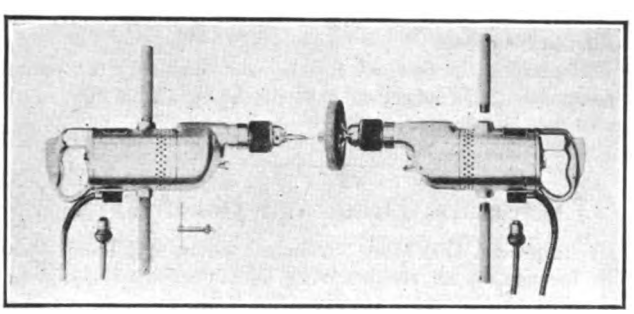
In starting the engine, when it is at rest, an adjustable spring raises the disk-valve proper, thereby permitting water to escape through by-passes to the waste-pipe. When the engine is operating, the disk valve is seated by the pressure carried in the steam chest, thus any excessive pressure accumulating in either end of the cylinder, due to priming or other causes, will instantly overbalance the pressure on the top of the disk valve, opening both cylinder drains and permitting water to escape from one end of the cylinder and, at the same time, relieving steam pressure in the other end.

Although the Diel-More Valve automatically performs the functions of a drain and relief valve, it has produced a marked saving of cylinder oil and steam, and greatly extends the life of packing in the stuffing boxes. It is made entirely of brass, and has only one moving part, the disk-valve proper. The spring that supports the disk valve is adjustable. The valve is fully guaranteed, and actual service over a long period has demonstrated that its efficiency of operation is not in the least impaired.

There is also a Diel-More one-way valve for apparatus that carries a high pressure, with only one outlet to be drained. This is automatic, but without the relief effect; it opens when the pressure is removed from the valve disk and closes when pressure is applied.

## Portable Electric Drill and Grinder

THE new "Wodack" Combination Portable Electric Drill and Grinder, made by the Wodack Electric Tool Corpn. of Chicago, has a drilling capacity of ⅛ to ⅝ in. in steel, and when used as a grinder carries a 6 by ¾ in. grinding wheel. Two speeds are provided, the slow speed for drilling and the



WODACK PORTABLE ELECTRIC DRILL AND GRINDER.

high speed for grinding. The complete weight of the tool is but 18 lb., while the motor develops ½ hp. under load. This tool is fitted with the switch located in the top handle, of the quick-make-and-break automatic-stop type, which insures control of the tool at all times. Aluminum castings and ball bearings are used throughout. The motor is of the Universal type, and therefore can be operated on both direct and alternating current of the same voltage.

## Dumorite a New Dynamite

A NEW "powder," known as "Dumorite," has just been perfected by the Du Pont Co. It is made with a double base of modified nitroglycerin and guncotton; it cannot freeze and does not produce headache. The Du Pont Co. announces that the explosive will effect savings of one-third on the dollar. It is as powerful stick for stick, under ordinary conditions, as regular 40 per cent. dynamite, and each case contains approximately one-third more sticks.

Dumorite is a free-running explosive. Tests have proved that it is especially adaptable for open work in quarries, construction and agricultural fields, for blasting hard rock and hard ores where the ventilation is good and for use in bituminous coal mines where a permissible is not required and where a large production of lump coal is desired.

## Industrial Notes

**Dayton-Dowd Co.**, Quincy, Ill., has opened an office at 809 Keenan Bldg., Pittsburgh, Pa., which is in charge of T. J. Barry, who has been connected with the home office for several years.

**Rathbun Jones Engineering Co.**, Toledo, Ohio, has appointed the Ingersoll-Rand Co., New York, general sales agent for Rathbun gas engines.

**H. W. Hardinge** sailed on Feb. 15, to attend to business of the Hardinge Company, especially connected with the Quigley Fuel Systems, in England, Belgium, France and Italy. He will return in about two months.

**McClellan & Junkersfeld**, 141 Broadway, New York City, is a new Delaware corporation for engineering and construction work. The incorporators are William McClellan, president of the American Institute of Electrical Engineers, Peter Junkerfeld, for many years connected with Edison companies of Chicago; and Horace T. Campion, of Philadelphia.

**William F. Parish**, 2010 Peoples Gas Bldg., Chicago, Ill., announces the opening of a petroleum analytical and experimental laboratory.

**American Carbonization Co.**—Howard R. Swearer, Edward C. van Asmus, Lloyd F. Schrader—has removed its offices to 212 5th Ave., New York.

**The Photostat Corporation**, 299 State St., Rochester, N. Y., has recently made some improvements in its "photostat," or photographic copying machine. The chief feature of the machine is its all-metal construction, making it durable and light in weight. The machine is made in the same sizes heretofore furnished.

## Trade Catalogs

**E. Vernon Hill Co.**, 64 W. Randolph St., Chicago.—Aerological instruments and the Psychrobook, which contains the psychrometric charts, 5-in. thermometer, absorbent paper, and note paper.

**Braun-Knecht-Heimann Co.**, 584 Mission St., San Francisco, Calif.—Bulletins describing portable prospecting and blowpipe outfits; metallurgical furnaces and burners designed for oil, gas, and gasoline; and laboratory machinery.

**Jeffrey Mfg. Co.**, Columbus, Ohio.—Catalog 345, Coal and Ashes Handling Machinery for Boiler Houses. Twelve types of Jeffrey power house equipments are illustrated and described in this catalog.

Bulletin 360. Portable Car Unloader.

**Hardinge Company, Inc.**, New York, N. Y.—Bulletin 12 on Quigley Fuel Systems, gives considerable space to the methods of preparing, transporting, and burning the fuel.

**Quick Repair Washer Co.**, Traction Terminal Bldg., Indianapolis, Ind.—Circular describing quick repair washer manufactured for mining machines, mine cars, etc.

**Pneumelectric Corpn.**, Syracuse, N. Y.—Circular describing the Pneumelectric Friction Hoist, which has been built for drag-line or scraper-loader service.

**By-Products Recoveries**, 328 Seventh Ave., New York City.—Bulletin 326, Dry Dust Collectors, Reverse Nozzle Type.

**Arthur D. Little, Inc.**, Cambridge, Mass.—Bulletin entitled Valuation Reports and Engineering Appraisals, which is sent out by the Valuation Department of the company, 330 Munsey Bldg., Washington, D. C.

**Triplex Machine Tool Corpn.**, 18 E. 41 St., New York City.—Catalog No. 1, Triplex No. 1 Machine Tool, for turning and boring, milling, thread cutting, drilling.

## EDITORIAL

### How Do Things Stand?

RIGHT after the Armistice and lasting to about the advent of spring in 1919, there was a period of gloom and depression out of which there came a concerted effort to start a "sunshine" movement. I shall be far from ascribing to this the ensuing boom of 1919–20, but it was contributory, and a vastly more severe penalty was paid than if things had been let alone. There are those who would like to institute something artificial now. This thought has drifted down to the classes that—well, that are not trained in economic thought. I attended a vaudeville a few nights ago where in the course of the entertainment a youthful gentleman, who was really serious, sang a song of which the several verses began with the words "Hello, Prosperity!" the burden of the subsequent advice being that if everybody who had a wad would loosen up and enter upon a career of profligacy hard times would soon be over, which sentiments were warmly applauded. Considering that professional Wall St. is in the same mood, we should not be hypercritical; but a "sunshine" movement, a renewed period of inflation, or whatever it may please anybody to call it, in the present juncture would be a real calamity.

There has been no improvement in economic conditions beyond the nature of little ripples on the surface of a lake. Indeed, the sober observer of world-wide affairs finds it difficult to avoid the conclusion that things are becoming worse. The recent studies of Bass and Moulton, Friedman, Keynes, and Vanderlip, together with my own, while representing views from different angles, are remarkably unanimous in their conclusions as to the gravity of the state of affairs.

About the best index of industrial activity is the number of workers who are employed. In Germany, where there is the greatest activity in Europe, the percentage of employment, according to the latest

Digitized by Google

reports, was about 97½. In the Netherlands it was about 92½; in Belgium about 86; in Great Britain about 83; in Norway about 81; in Denmark about 80; in Sweden about 73. Such data for the United States are not available, but more or less conjecturally we had a rate of about 87 per cent. at the minimum, and possibly it is about 90 per cent. now.

Percentages of employment have to be modified by factors of efficiency. There is considerable evidence showing general impairment of efficiency in Europe. In the United States there is a good deal of confusion on this subject. In some lines of work our men are now functioning with a high degree of efficiency; and in others not so. I should hesitate to venture into any generalization on this subject. It is clear, however, that we can make positively the generalization that among the workers of the civilized world there is at present a low degree of activity. In this respect the labor statistics are supported by the production statistics in so far as they are available.

Outside of these data it is clear, moreover, that an abnormal part of the world's capacity for production is being absorbed by the functions of government, which is a sort of negative production. The British governmental budget for the coming year calls for governmental revenue to the amount of about £950,000,000, which will probably be about one-third of the national production. The French budget also calls for about one-third of the national production. In the United States the cost of government—federal, state and municipal—is conservatively reckoned at the rate of about seven billion dollars per annum. Some authorities estimate eight billion. These figures include interest on debts, and in so far as the latter are internal, this implies merely the transfer of income from one group of people to another, but even after segregating such items there is in every country a greatly swollen absorption of the national earning power for the purposes of government. Manifestly, while this condition continues to exist, the ability of many people to save out of their earnings for the building of houses, railways, public improvements, etc., is curtailed.

A further curtailment results from derangement of the division of earnings among groups of workers, *e.g.*, as when the railway workers, controlling an essential function of economic affairs are able, by virtue of concerted action and the support of laws enacted in their favor, to maintain the capture by them of a disproportionate share of the national income. The railway workers are cited merely as an example, for there are other classes that have succeeded in doing the same thing. If those classes were generally thrifty, there would be no alteration in the national position as a whole, although there would be discomfort and discontent among the other classes that had been victimized; but when the favored or predatory classes, however one may please to characterize them, having appropriated the earnings that other people used to save, proceed to spend them for automobiles, moving pictures, phonographs and other luxuries, there is a direct subtraction from the national ability to create capital goods which is the only foundation of real prosperity.

We have, therefore, at the present time there major conditions of adversity, *viz.* (1) a generally low scale of activity; (2) the absorption of a greatly increased proportion of national earning power for governmental purposes; and (3) a derangement in the division of the proceeds of production which contributes to profligacy in expenditures. To these may be added that the overbuilding of industrial capacity, after causing a direct waste of labor and material through the creation of unnecessary plant, has saddled each overbuilt industry with an unnecessarily large overhead expense and has attached to each of them an unnecessarily large personnel.

Even in a country that suffered as little as the United States, and which is so rich, these conditions have had, and will continue to have, serious consequences. At first we did not notice them. When our house building was checked we had the normal surplus on which to draw. Similarly we made our railway plant answer our purposes by dint of crowding and at the expense of inconveniences and delays. We neglected repairs to our buildings and stinted the supply of fertilizers to our fields. Perhaps the most immediately evident of our decadences was in the impairment of our tramways, whereof we saw, in some cases, entire lines abandoned. The things that I have mentioned are not mere conjectures or matters of opinion, but are shown positively by statistics. All of this meant, of course, that we were living on our fat. We have done, and are doing, this in other ways. For example, in order to keep themselves going our manufacturers have had to reduce the prices for their goods. With little or no abatement in labor costs, in many cases the only expedient was to skimp in materials. At present many articles are paraded as being offered at pre-war prices, which may be true, but often they are not the pre-war articles, though they may look like them. When a man who used to get for $10 a pair of shoes that would last for 10 months receives for that price a pair that will last for only six months he suffers an economic impairment that is just the same as if he has to let his house decay from lack of painting.

Without any question the people of Europe have been reduced to a lower scale of living than they had before the war. I am inclined to think that we of the United States are also already on a lower plane, speaking generally. Of food and clothing we have enough for our needs; of housing, we have not; of transportation facilities, we have not. No one who is compelled to ride daily in the subways of New York is under any delusion that he is as well off in that particular as he used to be. Still less are those suburban dwellers who lost their trolley lines altogether.

Digitized by Google

Between the middles of 1915 and 1920 many classes of people came into the enjoyment of luxuries that they had never had before, but in the main that was at the expense of the national principal, as a whole. Since the middle of 1920, when the readjustment began, this benefit has been preserved by a few classes at the expense of the whole and especially more and more at the expense of other classes of workers. The favored classes consist largely of the members of labor unions, who number about 5,000,000 workers, including the members of the A. F. L. and the railway brotherhoods, together with those who are not at present paying dues but are regarded as sympathizers; and non-unionized workers in trades and vocations requiring long training, who have for that reason been able so far to withstand competition. These are the aristocrats of labor.

The railway workers, besides being banded in their unions, are protected by Federal laws. The grotesqueness of the situation is reflected by the fact that for some kinds of work for which the railways are required to pay about 40 cents per hour the outside market price for the same, in the same towns, is 25 cents. Some of the railways are meeting this condition by turning over branches of their work to contractors who can employ men at the going rate which they, themselves, having been macadoodled, are not permitted to do. This is not a story from "Alice in Wonderland."

The upshot of all this is that while the farmers and miners (including the mine stockholders) have lost their buying power, the prices for raw materials having shrunk to about pre-war levels (in some cases lower), the prices for goods at retail have come down but little, and when nominally they have it is frequently merely because the goods have been shoddied. The cost of having anything repaired is often prohibitive. So long as these weirdly unsound conditions obtain there is no ground upon which to base hopes for prosperity, or even a return of normality in business.

We can not have any return to normality until Europe is able to buy from us again in something like the old way, and that is far distant; but we can have great domestic activity in replenishing our depleted stocks of goods and in supplying the housing and transportation facilities that we need. That is not to be expected, however, until the existing maladjustments have been corrected. There is not going to be any enduring prosperity merely by invoking it, or wishing for it or kindling false sentiment.

The prevalent theory notion that business improvement will begin soon is based upon hope rather than reason and it is to be feared that it is being cultivated by those who expect to realize ephemeral profits from it. If such a premature improvement happens it will be harmful, for it will only delay the completion of the readjustment that alone can lay the foundations for permanent improvement. At the present time the "optimists," so-called, are mischief-makers. So are those who are planning great expenditures for highways and other governmental improvements with a view to making work; and so are those who may try to arrange compositions with labor, which if successful can do nothing but prolong the agony. The existing economic evils are not going to be cured by shouting "Hello, Prosperity!" but they will be overcome most quickly by facing the facts.

The present position of the American people may be summarized in this way: A diminished production, as compared with 1913; a curtailed export market; a greatly increased subtraction for governmental purposes (high taxes). Out of the remainder a disproportionately large allocation to certain classes of labor and by them continued squandering of the proceeds. These conditions are evident to anybody who stops to think about them. I have no doubt that they are appreciated even by Samuel Gompers. He is acting, however, in behalf of his particular group of about 4,000,000 union members and has his hands full in restraining the red, radical elements among them, which want to plunder.

W. R. INGALLS.

## Revision of the Mining Law

HEARINGS on the revision of the mining law before the House Committee on Mining were scheduled for the first weeks of March. Owing to the wide publicity given to the Arentz Bill, which was drafted by a committee of engineers appointed by the Bureau of Mines, a voluminous amount of correspondence and technical notice has been given to the details of this bill. Careful scrutiny of all of this material reveals some interesting facts. It is clear that most of the people who are criticizing the bill have not read it intelligently. Intelligent criticisms are to the effect that the time prescribed for holding a claim without discovery is either too long or too short, or that the method outlined for recording claims is too onerous, or not enough so, etc., etc. The large amount of aimless and sometimes vituperative criticism may be disregarded and notice taken only of the constructive criticisms. These pertain to practically five points.

A fundamental idea of the committee's bill is the abolition of the law of the apex. However, that can not be done without doing other things. With abolition of the law of the apex, abolition of discovery as a prerequisite to location follows necessarily, for otherwise there would be no means of locating the extension of a vein dipping beyond the vertical planes of the original location. Moreover, there are orebodies that do not appear on the surface at all, wherefore it is impossible to make any superficial discovery. With abolition of discovery as a prerequisite, it follows that there must be some time limit for holding a claim.

The committee, in drawing this bill, strove to pre-

Digitized by Google

serve the wealth of legal decisions that have been built up by years of patient application.

The question of requiring discovery as a prerequisite to location under the present law leads to moral corruption of everyone connected with the claim. Everyone knows that most locations are made where the discovery shaft can be sunk with the least effort and expense, and the discovery of mineral in place is in the majority of cases pure fiction. Under the new law a location can be held for five years without discovery and then on the annual payment of a stated fee can be held for another period of five years. This not only gives the old prospector all the opportunity which he has now of developing his property, without perjuring himself when he records his location notice, but it gives the large companies with capital an opportunity to do the extensive drilling that must precede the probable discovery of any large orebodies in the future.

If at any time during the original five years or the subsequent extension an actual discovery is made, the holder must proceed to patent within seven years from the time of the original location, unless extended by the exploring right to 12 years. There has been much misunderstanding about this section of the law which, like all the other misunderstandings, results from inadequate study and failure to comprehend what the English language plainly states.

The question of locating claims on cardinal lines is a minor one from the standpoint of the Revision Committee and will be conceded to the opponents without argument. It was suggested only as a desirable thing and not as an essential one.

The size of the mill sites has been a subject of misunderstanding. The little old five-acre mill site per claim, which was ample for a 10-stamp mill, is utterly inadequate for the large porphyry properties of today with immense tailing ponds and the disposal of overburden and stripping which has come to be a common problem to all steam-shovel properties. Under the present law it is almost impossible for an engineer or a company to obtain sufficient ground for these purposes without resorting to various subterfuges to accomplish those things which everybody wants to accomplish, including the prospector and the public at large, but is prevented from doing by the rigid but inadequate provisions of the law. In other words, under the new law an engineer and manager does not have to leave his conscience at home while he is accomplishing these necessary acquisitions of land. The criticism that it gives wealthy companies the opportunity to acquire and hold large acreages is the result of a non-understanding of the situation.

The matter of assessment work has aroused a storm of criticism; why, it is difficult to understand. The revised law does not take from the prospector the right he has at present to perform his annual assessment work if he chooses. Moreover, it does give him the privilege, now non-existent, of paying the assessment work in cash in lieu of this labor; money which does not go into a general fund but must be expended for the benefit of the district in which his claims lie. It may be spent in developing roads that will greatly benefit any subsequent work which he will do or for many other purposes that will be much more to his benefit than digging a hole in the loosest wash he can find on his claim. There is only one possible class of mining-camp men who can suffer under this clause, and that class is composed of those men, common to so many districts, who will undertake to contract the assessment work on a group of claims at $25 per claim and render a receipt for a record in the office of the mining district for $100 worth of work done per claim.

The revised mining law does not take away from the prospector or any other class any of the rights which they have under the present law. The section providing for vertical boundaries of claims is not retroactive and does not deprive anyone of any extralateral rights now being enjoyed. On the other hand, these vertical boundaries will insure to the holder of a claim any ore within his boundaries that might subsequently be discovered to apex outside of his line and which under the present law would then be taken away from him.

With abolition of the law of the apex, square claims are the natural ones; everybody seems to agree to that. Regarding the size of the claim, there was difference of opinion as to whether the unit should be 10 acres or 40 acres. The committee rather ingeniously provided for both. The people living in the Northwest, who were familiar with the large claims of British Columbia, wanted large claims; the miners operating in the Southwest, who were familiar with the small square claims of Mexico, wanted small claims. By making the 10-acre square claim the unit, the Southwestern miners got what they asked for and the Northwestern miners were satisfied because, by locating a number of these small units, they could get a claim of any size and shape they desired.

Of course there is no logical reason why there should be any difference in the manner of locating placer and lode claims; especially is there no difference when the law of the apex is abolished. The proposed bill does not cover phosphate deposits, petroleum, etc., for the reason that they are reserved under the leasing acts.

At the February meeting of the Mining and Metallurgical Society of America, Congressman Arentz was the guest of honor. He spoke at length and then joined in a round-table discussion of the merits of the bill and the points criticized. As a result a perfect accord seemed to be reached between the Congressman and the members of the revision committee present, and it is confidently expected that the points of irritation in the bill can and will be eliminated so that the very great benefits aimed at, not only for the general public but also for the mining profession, including the prospector, the mining engineer, and the operator, will be achieved.

## The Coal Strike

BY THE time this issue is out the coal strike will be well under way. It is to be hoped that it will not be accompanied by disorders. It is to be hoped, moreover, that efforts toward compromises will not be successful.

This thing must be fought out, and the sooner it is brought to a sharp conclusion the better will it be for everybody, the coal miners, themselves, included. Our industries have got to have cheaper coal. So have the inhabitants of those sections of the country wherein anthracite coal is the chief domestic fuel.

Those misguided persons, carried away by their emotions, who are talking sympathetically in favor of the coal miners, do not appreciate that they are counselling expedients that are contrary to the interests of the American people in general. If the anthracite operators deserve any criticism, it is for the moderation of their proposed reduction of wages. Anthracite coal has got to be furnished to the consuming public at very much lower prices than even the new wage scale will permit.

It is contrary to the public interest to have consummated a contract between operators and miners that will maintain high prices for an indispensable commodity over a term of years, for the benefit of classes of people who are exceedingly few in number in comparison with the whole; not even if such contract results in some abatement of the extravagantly high prices that the consumer has had to pay heretofore.

W. R. INGALLS.

## A Code of Ethics for all Engineers

THE members of the Institute have been requested by a resolution of the Board of Directors to comment on a Code of Ethics. This Code was presented to the Board in February and again in March, and in the meantime was published in the March number of MINING AND METALLURGY. The ethics of the mining engineers stand as high if not higher than those of any other profession; the very nature of mining engineering and the relations of the mining engineer to his client make this not only necessary but natural. The mining engineer's judgment and integrity are worth much more to his client than his ability with a slide rule. The mining world is comparatively small and while mistakes in judgment may be forgiven, lapses from the narrow path of rectitude never are. However, it is proper to promote the ethics of the engineering profession at large by coöperation in formulating a code for general adoption. Careful scrutiny of the proposed code is urged and criticisms are solicited. The resolutions adopted by the Board are as follows:

WHEREAS, a Joint Committee of Engineering Societies has submitted a Code of Ethics for Engineers and asks its adoption by the governing bodies of the four Founder Societies, and

WHEREAS, the said Code of Ethics has been published in the March number of MINING AND METALLURGY, the official organ of this Institute,

BE IT RESOLVED: That the Board of Directors of the A. I. M. E., while agreeing in principle with the Code as proposed, believes that it should not be definitely adopted by the Board without giving the membership at large a full opportunity to discuss the subject, and propose possible modifications which might adapt the Code to the special conditions of the mining profession, and

RESOLVED, that a copy of this action of the Board of Directors be published in the April issue of MINING AND METALLURGY, with the request that members send their comments to the Secretary of the Institute.

Although several of the national societies have codes of ethics of long standing and the Institute has never adopted one, the Institute is the only one of the national societies to have expelled members for unprofessional conduct.

PERCY E. BARBOUR.

## Division of Petroleum Technology

AT THE March meeting, the Directors of the Institute authorized the formation of a division within the Institute to be known as the Division of Petroleum Technology. It is hoped that the formation of this division will serve to bring the members of the Institute who are interested primarily in oil and gas into a more compact group and thus promote more effective action by them on their various problems.

In choosing petroleum technology as their especial province, it is the intention of the oil and gas group to occupy a field not at present occupied and to do everything possible to advance more effective methods for the production and utilization of oil.

For the purpose of this division, the term technology is construed in its broadest possible significance, so as to cover the production, transportation, refining and utilization of petroleum and its products, and will include, as heretofore, geology, the technology of drilling and production methods, transportation, refining, fuel utilization and a broad study of possible sources of petroleum.

The present Petroleum and Gas Committee of the Institute has been authorized by the directors to take the steps necessary for the formation of such a division.

E. DEGOLYER.

## Patent Office Relief Bill

OWING to an unfortunate inadvertence in the printing office, the word "patent" in the title of the short editorial on this subject in the March magazine was made to read "patient." One of our members has written to us about it, asking if it was *mal à propos* or malice *propos*. It was accidental, however *propos*.

We are informed that the entire force of 1016 employees of the Patent Office, who certainly have been "patient" during the long period of neglect and lack of appreciation, are jubilant over the long-sought recognition and that the resulting increased morale is already making for a more efficient and expeditious handling of the public business.

# Review of the Month

DURING the month of March there was some lifting of the veil, revealing somewhat of the maelstrom in the economics and politics of the world. Great Britain was in throes of political controversy, with threats of resignation by Lloyd George and a general election to ensue. Ireland was uneasy with internecine squabbles. The leaders of the opposing sides have been summoned to London for a conference which Parliament believes offers the only hope of a solution of the present difficulties.

France, awakening more and more to grim realities, learned of a budget for 1922 calling for more than 50 billion francs, or nearly one-third of the estimated national production, with the prospect that after this deduction is made there will be nothing left over what is required for the immediate support of the people, and that on a reduced scale.

Germany, although hard at work, found itself coming closer and closer to financial collapse and repeated its intimations that it would be unable to keep up with the provisional payments of 31 million gold marks to the Reparations Commission every 10 days as arranged at Cannes.

Russia suffered more acutely from the famine and there were evidences of political insubordination among the Ukrainians.

Egypt was in trouble arising from determination to win independence. About the middle of March the complete independence of Egypt was established and that country passed into somewhat the same relationship toward Great Britain that Panama has to the United States.

At the head of the Adriatic, Fiume came into notice again with disorders threatening to produce conflict between Italy and Jugoslavia.

In the Near East there were forebodings of trouble through resumption this spring of the war between Greece and Turkey.

The Government of India informed the British Government that the intensity of feeling of the Moslems of India would make advisable revision of the Sèvres treaty between Turkey and the Allies. It urged evacuation of Constantinople and the restoration of the sovereignty of the Sultan over the holy places and the reestablishment of the Turk in Thrace, Adrianople and Smyrna. The publication of this report by Mr. Montagu, Secretary of State for India, on his own responsibility led to his expulsion from the ministry. Following this, orders were issued for the arrest of Gandhi, the leader of the agitation in India. That was effected on March 10 and he was sentenced to six years imprisonment.

All over the world, there were labor troubles. In Australia the long contest between employers and workmen seemed to be coming to a head. In Italy there were riots between the Fascisti and Socialist elements. At Genoa the labor unions declared a general strike. In Spain labor troubles began to brew, owing to the movement toward wage reductions that were necessary to enable Spain to maintain its export trade. In South Africa the miners' strike in the Transvaal, which at the end of February appeared to have been conquered, broke out with increased intensity, attended with violence, and threatened to involve the entire Commonwealth. About March 10 there were armed conflicts in the Transvaal and things looked very much like a rebellion against the Government. After a pitched battle the insurrection was put down and the strike came to an end.

Economically, every country of the civilized world, with the sole exception of Germany, is characterized by a high percentage of unemployment. With that situation there can be no prosperity, for there can not be adequate production, nor normality of trade, if large percentages of the people be idle; nor can there be while the several governments maintain profligacy in their expenditures. In the United States the strike in the textile industry of New England has spread and the coal miners' unions of several of the states voted to strike on April 1. By the time this page is printed a general coal miners' strike will doubtless have begun.

The overshadowing political event in the United States was the introduction of the soldier bonus bill in a particularly deceptive and vicious form. It was passed by the House by an overwhelming majority.

Another important event was the declaration that the United States would not participate in the Genoa Conference, although intention to hold aloof from European economic affairs was disclaimed. We may discern in this an American diplomatic policy of enforcing military economies in France; and by refusing to talk with Lenin and Trotzky, while professing friendship for the Russian people, to contribute to the development of political changes in Russia. Good opinion as to Russian affairs is to the effect that the Bolshevists are on their last legs and are playing desperate cards.

The American troops were ordered home from Germany and Secretary Hughes demanded of the Entente recognition of the American claim for the cost of having maintained these troops on the Rhine.

The Senate finally ratified the Four-Power treaty insuring peace in the Pacific.

# Prospecting and Research*

By ARTHUR S. DWIGHT

President, American Institute of Mining and Metallurgical Engineers

WE DO NOT have to go so very far back, when measured in actual years, to what may be considered the beginning of the industrial era of the great West, the discovery of gold in California in 1848, just 74 years ago. By a strange coincidence, this event occurred within a few days of the signing of the treaty with Mexico which ceded California to the United States. Needless to describe the mighty wave of humanity that hurled itself toward the setting sun in response to that call. The single thought in every one's mind was *gold*. The gold as they found it in placers or ledges could be so easily worked, and the product was so readily transportable, and available immediately as money, that practically no attention was paid to deposits of the base metals, in the treatment of which cheap transportation was a paramount consideration; consequently little progress was made in anything but gold mining until after the Civil War.

The next great step was accomplished when East and West were united by the successful construction of the Union Pacific Railroad from Omaha across the great plains and through the Rockies to meet the rails of the Central Pacific coming eastward across the Sierras. The industrial history of our great West really dates from the day when those two bands of steel were joined, on the shores of the Great Salt Lake at Promontory Point, May 10, 1869. That seems a long time ago when we think of the enormous changes that have been wrought since that day, and when we regard the rich empire that has sprung up in that western land.

Into the new empire thus made accessible, by this first thread of steam transportation, flocked a new brood of adventurous spirits from the older communities of the East.

This way walked Fate; and as she went, flung far the line of destiny,
That bound an untracked continent to brotherhood from sea to sea;
That long gray trail of dream and hope, marked mile by mile with graves that keep
On every barren hill and slope some stout heart lost in dreamless sleep.
Patience and faith and fortitude were willed to it and justified;
Stern, homely virtues, plain and rude, eternal as the sky and wide.
Nor ever sea-king dared the sea in sterner mood than these who went
Strong armed to wrest from Mystery their birthright, half a continent.

* Inaugural address at Banquet, Feb. 22, 1922.

And so the prospectors multiplied. They swarmed over the hills, still searching for gold by preference, but taking more and more notice of other metals, especially as transportation became easier. With every discovery a mushroom city would spring up almost over night, perhaps to be abandoned to the coyotes and rattlesnakes when the next mad rush followed a new discovery elsewhere. It was a great drama, this breaking of the trails and the winning of the West. The prospector is the hero of the play.

T. A. Rickard has put the emphasis in the right place when he says:

> The fur trader traversed the snow-clad plains and penetrated the pine-clad mountains of the Canadian Northwest; the salmon fisher sailed into the long estuaries; but neither of them touched the heart of that great lone land. Not until the pick of the miner awoke echoes that had slumbered since creation did the vast solitude respond to pulsations of human endeavor. Hunters, traders, even soldiers and farmers crossed the prairies from the Mississippi to the Rocky Mountains, and adventured over the desert to the Pacific Coast. They carried the flag, and they hoisted it over the new dominion, but it was an empty conquest and a vain annexation until the miner spoke the word that set the world aflame.

As the ores of lead and copper containing the precious metals came to be mined, only the richer ones that could stand transportation to distant smelteries in the East or to the refineries of Europe were shipped, but the bulk of the mineral wealth that was thus uncovered had to await the establishment of smelting plants near at hand. The 80's and 90's witnessed a great development of the smelting industry, especially in Colorado, Utah and Montana, and the men trained in that school of metallurgy have shaped the practice of the whole world in non-ferrous metallurgy since that day. The low rates for smelting which resulted from the keen business competition for ores, coupled with very low freight rates, developed an enormous metal output in the Rocky Mountain region, and acted as strong encouragement to continued prospecting. Mexico also was only awaiting the coming of railroads and smelting plants to yield up her mineral treasures.

In all of this impressive development, it was the prospector who, with tireless activity in the eager search for new districts, kept the mining industry supplied with new material and opportunity for profitable exploitation.

It was notoriously thankless work. Seldom did the prospector, even though lucky enough to "strike it rich," reap the final reward that his indomitable

Digitized by Google

courage, self sacrifice and self-imposed hardships should have entitled him to receive.

As "the blood of the martyrs was the seed of the Church," so the unrequited toil and hard fate of the prospector was the cornerstone of the mining industry, and his work constituted a fundamentally important stage in the growth and maintenance of the business. Into that stage was concentrated an incredible amount of non-productive labor and wastage, waste of human hopes, waste of human lives. No money could buy such effort; no hireling would have endured it; none but an enthusiast, a dreamer, could have stood the pace.

It was almost invariably the man with the money, who came later, the capitalist, whether an obscure shopkeeper in a mining camp, furnishing the grub-stake, or the dealer in millions who supplied the business talent and the capital necessary to develop the discovery into a profitable enterprise, a going concern, who claimed the credit and reaped the reward.

### Rosy Romance of Prospector

But rough and obscure as was the prospector, a rosy cloud of romance has always hung over him as he is popularly portrayed. He is classed with the heroes of poetry and history, with Jason's Argonauts in search of the Golden Fleece, with Hercules seeking the golden fruit of the Hesperides, with Marco Polo, Columbus, Magellan and the other dauntless spirits who opened up the world to our use. Certainly he has many points in common with them, but especially his ever-present hope of a rich reward to be won by his individual courage and striving.

But the old breed has disappeared into the limbo of the past, along with the red man and the buffalo; vanished before the very tide of civilization and progress of which he was the forerunner, and indeed which he himself evoked. His epitaph might be fittingly written in another aphorism by the author just quoted: "Trade follows the flag, but the flag follows the pick."

I shall not attempt to further eulogize the prospector. That has been done by lips more eloquent than mine, but rather, after acknowledging the great debt that the mining industry owes to him, to brush aside for a moment the mists of romance, and see some of the serious consequences to the industry of his passing.

We have heard many discussions of late concerning the decline of the mining industry, its whys and wherefors. I shall, of course, ignore the temporary commercial conditions that have caused the present industrial stagnation, for I am contemplating only certain phases of the general underlying conditions.

While there are doubtless many factors that could be named as contributory causes for this decline, such as exhaustion of certain mining districts, high wages, scarcity of labor, unwise mining and land laws, restrictive legislation, and others, the principal cause undoubtedly is that we have not been replenishing our mineral reserves by the discovery of new mines and districts as fast as we have exhausted the old. We have been "burning the candle at both ends;" though the inevitable consequences have been considerably delayed, and the situation somewhat mitigated by the progress that has been concurrently made in the methods of ore treatment, whereby ores of lower and lower grade could be treated at a profit. Each generation of metallurgists has been able to work over the mine dumps that were rejected by their predecessors, and the end is not yet; but the metallurgist has outstripped the miner, and with present facilities there is a serious dearth in mineral supplies.

The outcome is bound to be as inevitable as the laws of logic can make it. The prospector set in motion forces far beyond his ken, and these forces were to gather momentum and sweep him from their track. He had created a machine that outgrew his power to control, and he must needs step aside. The restraints of the civilization that grew up around him were too onerous for his free, untrammelled nature, and on the other hand, civilization had no patience with such an example of hopeless inefficiency. Hemmed in on all sides by the expanding boundaries of prosperous communities, with his beloved hills and forests appropriated as forest reservations, subject to perplexing rules and regulations, placarded with advertisements of patent medicines or improved breakfast foods, he felt that the very air of the mountains had been preëmpted, and he fled, we know not where. Thus, the very conditions that made for perfection in the industry furnished also the microbe of decay. With our efficiency engineers and our campaigns for the elimination of waste in the industry, we have indeed succeeded in producing cheaper metals, but we have at the same time eliminated the most wasteful single factor, though the most necessary, of the whole industry, the prospector. That is what is the matter with mining!

### Research in Broadest Sense the Remedy

What is the remedy? My answer briefly is *Research*, research considered in its broadest sense. Not the ordinary conception of hiring a young chemist to make a few analyses, though that may be a very useful thing to do, but the awakening of a general spirit of research, the habit of mind that does not take things for granted simply because *they are*, but that cultivates the power of observation and correlates facts old and new under the direction of imagination tempered by ripe technical experience. Imagination alone is a dangerous guide, but as an ally to sound judgment it is unconquerable. Napoleon said "Imagination rules the world." We of the mining profession need to develop more generally the trick of constructive imagination.

A witty person has said that Boston is not merely a city; *it is a state of mind.* If we could develop a state of mind conducive to research in this sense, the whole mining industry would be pervaded with a lifegiving

Digitized by Google

atmosphere, and a renaissance of creative effort would be sure to result.

Turning now to the practical side of the question, it is evident that we cannot any longer depend upon the knight-errant prospector to keep us supplied with new mines. We know that the surface indications have been everywhere in this country so closely scrutinized that there is decreasing likelihood of new discoveries at grass-roots, but any mining man looking back on his own experience must realize that many an abandoned prospect he has seen was the victim of ignorance, bad observation, lack of courage, or of financial means. There are undoubtedly many such prospects that would amply repay further exploration and intelligent consideration. Deep exploration from existing mines will also develop new ore supplies.

In general, however, we may say that the situation is a serious one, and we must look to the inventor for the remedy. He must find us new means for conducting our prospecting, and improved methods of ore treatment.

In what I am about to say, please do not understand that I would overlook for a moment any of the present standard methods of ore discovery in favor of something untried or fanciful. In the last analysis, the most potent talismans are the faithful old pick and shovel.

Neither would I scrap the old methods of ore treatment; quite the contrary. Simplicity is a cardinal virtue that should not be lost sight of either by the miner or the metallurgist, and I would seek for inspiration by going back to a study of the older and simpler processes, and see if by a comparative criticism in the light of modern technical knowledge, their weak points could not be strengthened, their strong points reinforced and their causes of failure removed.

### Latent Possibilities in Materials

As a matter of fact, we have at our command an enormous store of latent possibilities in the way of new materials of construction, fuels, refractories, new substances capable of an infinity of chemical reactions, properties of matter and elemental forces formerly unknown, and means for accurate measurement and control of conditions, the importance of which we do not begin yet to adequately comprehend. Every single new discovery along these lines opens up entirely new fields of possibilities for improvement of old methods or the creation of new.

What we need is first a knowledge of the facts; second, the intellectual vision to see its application to the practical problem; third, sound critical judgment, capable of discriminating between the foolish and the useful; and finally, the patience and courage to put the idea through to a commercial success.

It is not only along mechanical lines that we need stimulation. We must look to the geologist to shape his studies more and more toward the practical requirements of the miner, and to change his rôle from that of historian after the fact to that of prophet and leader. He must find a way to tell us the nature of the hidden orebody and its relative richness by reading the handwriting of Mother Nature that he finds in the weathered rocks of the outcrop, or the neighboring rocks of the deeper workings, so that the miner may confidently follow his indications. He must discover the Rosetta Stone that will furnish the key to interpret these hieroglyphics of the Earth Gods.

Then again, the inventor may find us a way to locate hidden ore by enlisting the aid of some of those mysterious agencies that are now at our command, strange vibratory things, like the genii of the Arabian Nights, that can penetrate cosmic space or terrestrial substance with swift purpose, and which are being made to increase a million-fold the delicacy of the five human senses. It sounds fanciful, the idea of seeing into the ground, or perhaps listening to the whisperings of the rocks, or reading the message of the earth currents, but we must admit that stranger things have happened in our own time.

### Present Possibilities in Metallurgy

In the field of metallurgy the possibilities are still more evident. The research work that is now being done, and there is a good deal of it, is concerning itself principally with the products rather than with what may be called the grand problems of metallurgy. There is a crying demand from the trade for improving the quality of the metallic products, eliminating impurities, forming new alloys with special properties, but established industry is instinctively conservative when it comes to anything that might threaten the value of existing plant investment; it is inclined to let well enough alone, and let the other fellow do the experimenting if he wants to. The thought of fundamental changes in process or apparatus, therefore, is not always a welcome one, and comparatively little encouragement is offered for this kind of research on the larger working scale necessary for the convincing demonstration of any new process. This is natural enough, but does not make for progress. One trouble is that the manager is seldom the owner, and if he has the vision, he seldom has the power to make any sweeping change, even though he might be thoroughly convinced that his company would make money by scrapping the old plant. All these questions depend in the last analysis on the human factor, for a skilful metallurgist will produce better results with a tumbledown out-of-date plant than his less resourceful neighbor may with all the modern improvements.

There are some notable exceptions to this general neglect of research, and the names of several large companies that are already carrying out a broad-minded policy in this respect will instantly occur to you. It is

Digitized by Google

a notable fact that in the plants of these companies there is to be observed the zeal for research in all departments, from the furnacemen to the manager, and it is safe to say it extends to the stockholders also, whose consent is a necessary factor. When the stockholder becomes convinced that his future dividends depend on the encouragement of research, just as the life of a mine depends on spending a certain proportion of earnings on development work, we shall find this atmosphere a prevalent one. Meantime, the engineer can do much to advance that time by his individual efforts, and by proving that it is worth while financially.

It is pertinent at this point to mention the excellent research work that is being done by the U. S. Bureau of Mines at its various experimental stations. The Bureau has published some valuable studies in special metallurgical methods. Just how far these results have been utilized, I cannot say, but they ought to be of great benefit in suggesting opportunities for further effective research by individuals to meet special problems. I venture the opinion, however, that it is much like all the other aids that come too easily and are not appreciated.

### Industrial Progress and Individual Striving

Prof. Elihu Thompson has truly said: "Publish an invention freely, and it will almost surely die from lack of interest in its development. It will not be developed and the world will not be benefitted." This leads up directly to the main point I wish to make. Industrial progress is gained only by individual striving. It is a long shot from an idea, however good, or a paper patent, however well drawn, to a going success, and few who have not been through the mill can appreciate these words. Almost every epoch-making invention was pronounced a failure at first, and it is only the unconquerable enthusiasm of the inventor, and his steadfast ability to meet the financial and moral strain, that saves the idea to the industry.

If the world is to profit by this fine constructive spirit, we must take our lesson from the prospector, and appeal to the same instinct that led him in his tireless search for gold. Call it greed, if you will, but it is a noble form of greed, for it seeks not to profit by taking that which is another's, but by creating new benefits to man, and making two blades of grass grow where one, or perhaps none grew before. The possibility of riches is one of the greatest incentives that can touch and animate the human mind, and inspire human endeavor. No hireling will do what a man will do who is to profit directly by his own efforts in proportion to his success.

Even the soulless corporation is amenable to the same urge, for it is hope of greater gain that dictates its course. It is wise indeed if it clearly recognizes the continuity of this principle and the importance of this trait of human nature by offering to its employees well defined rewards for successful ideas. It will be still wiser if it enlarges its corps of helpers and offers adequate inducement to independent workers on the outside to furnish solutions to certain definite problems. Put a premium on ideas, and they will be forthcoming. The fact that the incompetent and the over-enthusiastic might take advantage of such an open-minded attitude should not militate against the principle. One always has the right of choice, and can say "no" to a wild-eyed inventor as easily as he can turn down a mining prospect. Commercial success should be the final arbiter in all cases.

Wise patent legislation is an important factor in such a plan, but actual accomplishment and beneficial use should always be allowed to outweigh the sterile, unused idea which lies dormant in the patent office until some one comes along who has wit enough to make the idea effective. The patent office is filled to suffocation with such half-baked ideas which are worse than useless because they simply obstruct progress by causing litigation.

We have had some recent instances of large corporations possessed of important holdings of ore, with great potential value in metals but not amenable to ordinary methods of extraction, courageously attacking their special problems and, by following these very principles, working out satisfactory solutions. I might mention the electrolytic zinc process at Anaconda, the leaching of the copper ores of the New Cornelia company in Arizona, and the copper-leaching problem at Chuquicamata, Chile, as outstanding examples of well-directed team work.

So I believe it is possible to solve many of the pressing problems that confront our mining and metallurgical industry by first diagnosing those problems clearly and then holding out adequate rewards for successful solution, at the same time surrounding the industry with such conditions as will encourage and not hamper the free exercise of the inventive faculty. Thus shall we eliminate, as far as possible, the wastage and cruel disappointment that was so often the lot of the pioneer prospector, and we shall retain and foster the vital element that was his glory; his strivings, his patient courage and his fine contempt for privation and danger.

Necessity is not the mother of invention, any more than she was the patron saint of the prospector. The Prospector and the Inventor are twin brothers, and Hope is the mother of both. We take off our hat to the prospector.

Stern school of heroes unconfessed; unweighed for meed of right
or wrong;
By glib late-comers dispossessed of honors that to them belong;
As in the fire tried hour, strange warring elements will fuse
To purpose, unity and power, to truer strength and noble use—
Unconscious, save that here was life a man might live as manhood
meant,
They wrought a nation from their strife, and shaped it with their
discontent.

# Progress and Literature

By J. R. FINLAY

Consulting Mining Engineer, New York City

THE other day, I fell into conversation with two gentlemen who desired to improve the condition of the people; so that the talk was semi-political. They seemed to agree that I was inclined to be "conservative," "reactionary," perhaps an "evolutionist," looking upon "reform" with suspicion. Finally I rejoined somewhat in this manner:

"You attach to me phrases that I have heard all my life but which convey no meaning to me. It is quite true that I do not make a fetish of terms like reform, liberty, democracy and so forth; neither do I worship the idea that 'things are good enough as they are,' 'leave well enough alone' and so forth. There is more satisfaction in building something up than in tearing something down, or in just maintaining something that is already built. Progress is a popular word; but what is progress? In my opinion it is comprised, so far as public welfare is concerned, of two elements: Improvements in production of goods and knowledge; improvements in keeping order."

This substitute for politics, economics, reform, progress, conservatism, radicalism, democracy, socialism, monarchism and all the phrases of public welfare may seem over-simple; perhaps it is, but at least it defines something. It seems to me to be at least worth attention.

## Artistic and Useful Production

If we define production of "goods and knowledge" as embracing all efforts that are worth anything we cover automatically the range of the human intellect. The painting of a picture or the making of a poem is as truly production as the reaping of wheat or the construction of a table on which to eat the bread that comes from the wheat. A poor picture or poem is to be compared merely to poorly cooked bread or to a commonplace table; they may go under the name of art, but are no more art than bad cooking. The best painting or poem may claim higher artistry than the best cooking; they are more permanent; but if poor cooking gives rise to physical indigestion, so the pretense of art under the name of literature, or anything else, brings on mental indigestion, which is far worse; for the first may give a drowsy spell or a stomach ache to a few people, while the second may give ills to the body politic such as will spoil the happiness of millions. At any rate, it does not seem to require very abstruse analysis to arrive at the conclusion that production is the result of putting the mind to good use, that the most valuable production comes from the best minds; and conversely that the best minds are the most productive—whether we measure production in manufacture of articles, in thought or in imagination.

## Good Government Aids Production

As I drove my automobile in Los Angeles the other day, my small boy asked me how I should like to be a traffic policeman. I answered that I would not like it because I would rather do something more productive; but after some pause I decided to take that statement back quite emphatically. I thought of Mexico and of Russia. The policeman was keeping order; preventing accidents, saving other people the loss of time: not directly productive, but indirectly exceedingly productive. In a country like this, where we have been taking reasonably good order and reasonably good government for granted, we are apt to forget that those are the greatest possible business assets, and the only way we have to remind ourselves of their value is to consider the condition of some country where they are absent. What is property worth in such a country? What reward does one get for his efforts, physical or mental?

Lincoln, on hearing himself called, very likely in compliment, a common looking man, said: "The Lord prefers common looking people; that is why he makes so many of them." The common looking common people of all countries are scantily provided with goods—they can use more; they do not enjoy anxiety; they like to be able to go about without carrying a gun; their personal freedom extends only to the frontier of the realm of order. To melt in an ecstasy over liberty and democracy while one is afraid to say what he believes, to work as he thinks is fitting, or to go out at night as he thinks he ought, does not seem to help a common looking man to get along in the world; and it may be doubted whether those words will give him permanent satisfaction or pleasure.

The mainstay of genuine progress can be nothing less than a great group of men, numbered by millions in any great nation, numerous enough surely to be called common, who are the guardians of common sense; the progenitors, recognizers and followers and choosers of sound leadership, who distinguish substance from show, logic from vaporing; who realize that to support and improve prosperity and order includes the development of all the capacity of the human brain.

Digitized by Google

It seems to me that a great society of technical men like the American Institute of Mining and Metallurgical Engineers represents to a fair extent leadership among such plain people of this most productive country. This is not intended for flattery or for hyperbole, but for a plain statement of the plain truth. I am sure its members have used their influence for the development of genuine productiveness; for the extension of fair play and good order such as make prosperity possible. We may properly be anxious that they shall continue to use their influence in the same direction, not by expressing cut-and-dried, arbitrary, narrow or intolerant opinions, however sincere or well meant, but by deepening and widening if possible the foundation for sound thinking and respect for the truth. It strikes me occasionally with a sort of alarm that for two or three generations we have been taking our government and order for granted; that our conception of the fundamentals that underlie them may have wilted; that the country is not so safe as it once was against gusts of hysteria, vagaries and artificial prejudices; that, in short, in a few generations more we may come in for a period of disorder and civil war.

Some people complain that the Institute TRANSACTIONS are a jargon of technicalities, uninspired, materialistic, built upon an imagination restricted to efficiency and accuracy, unresponsive to sentiment and taste, measured in dollars and cents. If this is not true we should have an intelligent answer for the charge; if it is true we should try to correct it. I am inclined to think that we have put too much faith in technology and too little in human interests. In order to picture how far we may have wandered in one direction, let me quote some sentences from George Bernard Shaw's "Back to Methuselah" which will make it plain how far some people have wandered in another:

> But meanwhile—and here comes the horror of it—our technical instruction is honest and efficient. The public school boy who is carefully blinded, duped and corrupted as to the nature of a society based on profiteering, and is taught to honor parasitic idleness and luxury, learns to ride and shoot and keep fit with all the assistance and guidance that can be procured for him by the most anxiously sincere desire that he may do these things well, and if possible superlatively well. . . . The result is that powers of destruction that could hardly without uneasiness be entrusted to infinite wisdom and infinite benevolence are placed in the hands of romantic schoolboy patriots who, however generous by nature, are by education ignoramuses, dupes, snobs and sportsmen to whom fighting is a religion and killing an accomplishment; . . . financial parasites on the money market, and merely stupid conservators of everything that exists merely because they are used to it, is obtained by heredity, by simple purchase, by keeping newspapers and pretending that they are organs of public opinion, by the wiles of seductive women, and by prostituting ambitious talent to the service of the profiteers, who call the tune because, having secured all the spare plunder, they alone can afford to pay the piper.

Really, I do not know whether this tirade is intended to be taken seriously or not. My impression is that it is deadly serious but spoken in the manner of jest. I call attention to it mainly because it is an example of literature, from the fountain head, that lives on phrases that represent half thoughts and whole prejudices. Papers, magazines and books are full of them: profiteer, militarist, parasitic idleness and luxury, imperialists, financial parasites, stupid conservators, seductive women, prostituting ambitious talent, spare plunder—all occur in one sentence. Similar phrases occur elsewhere in a whole type or style of literature: radical, capitalism, socialism, pacifism, industrialism, Mohammedan, Catholic, Protestant—simply words that come to be accepted as banners of allegiance or as objects of loathing and denunciation. To repeat them is to sound the tocsin of prejudice, for or against. At present they seem almost harmless, although they were far from harmless during the war; but let one look through history to see how seriously such phrases have been taken and how, over the chimeras that they represent, prosperity has been ruined by cycles of civil discord.

## International Geological Congress

THE 13th International Geological Congress will meet at Brussels, Belgium, Aug. 10–19, 1922. Any person interested may take part in the meetings and in the excursions during the days of the Congress, irrespective of professional qualifications. There will be excursions of special geological interest from Aug. 1 to 9, and from Aug. 21 to Sept. 3, but these are limited to professional geologists, geographers, mining engineers and others interested in the study of one or another branch of geology.

The official language of the Congress will be French, but papers and communications in English are admissible. Anyone who wishes to offer a paper or who desires information regarding the Congress is requested to write to the General Secretary at the Service Géologique de Belgique, Palais du Cinquantenaire, Brussels.

The Committee of Organization has decided not to admit applications to take part from nationals of those countries lately at war, in defiance of treaty obligations, with Belgium.

## Spontaneous Ignition of Coal in Storage

THIS subject is well summarized by J. F. Springer in *Combustion* for February. Anthracite coal is practically immune from spontaneous ignition. Bituminous coal under certain conditions of storage gives a great deal of trouble. Factors promoting self-ignition are:

1. Fineness; a slack coal presents greater surface for oxidation and also ignites more readily.

2. Depth of storage pile; as the dispersion of heat is retarded by deep piles. A depth of 20 ft. is unsafe, while no trouble is to be expected in piles less than 12 ft. deep.

Submergence of stored coal under water is the usual method of preventing ignition.

# Blue Powder in Zinc Smelting

By W. R. INGALLS
Consulting Engineer, New York, N. Y.

SOME months ago, I had occasion to make an investigation that introduced the subject of blue powder that is produced as a byproduct in zinc distillation. Although every zinc smelter is aware that more or less blue powder production is inevitable and there is a common practice as regards the treatment of it, the specific and quantitative data respecting the subject were more imperfect than would have been expected. I had reports from eight important works. Some of the data were especially determined for my investigation.

Speaking generally, there is a good deal of uniformity in the figures, all of which show that the blue powder product bears a large proportion to the ore originally charged into the retorts; that a large proportion of the retort capacity is devoted to the redistillation of blue powder; and that of the spelter product of a furnace about 30 per cent. is derived from blue powder, *i.e.*, it is zinc that has been distilled twice. The figures from the works are given in the following table:

| | Per Cent. Retort Capacity Devoted to Blue Powder | Per Cent. Spelter Made from Blue Powder | Per Cent. Blue Powder to Ore | Assay of Blue Powder Per Cent. Zn |
|---|---|---|---|---|
| A. | 22¼ | 32 | | |
| B. | | | 35 | 51 |
| C. | 23⅓ | 30 | | |
| D. | | 30 | | 62½ |
| E. | | 24½ | | |
| F. | | 33⅓ | 50 | |

In American zinc smelting terminology, blue powder is different from what it is in the European. In Europe blue powder is finely divided metallic zinc, more or less oxidized, which is collected in the prolongs. This is blue powder, strictly speaking. It is formed in relatively small quantity and is of relatively high grade in zinc.

In America it is the ordinary practice to throw in one pile the blue powder coming from the ladle skimmings, together with the retort samplings, condenser scrapings, condenser chips, and floor sweepings. This produces a large weight of material of low grade in zinc on the average.

I judged from the correspondence that many smelters have not given critical attention to this subject. One smelter (works G) caused a furnace determination to be made, with the results shown in the second table.

In this case, byproducts that have to be rehandled amount in weight to about 50 per cent. of the weight of the ore (19,000 lb. charged into the retorts). This appears to be an unusually high proportion and that is reflected in the low average in zinc of these byproducts, which is only 21.67 per cent. In the treatment of an ore charge assaying 72 per cent. zinc, the extraction of metal is 12,450 lb., whereof 1850 lb. may be estimated as coming from the byproducts and 10,600 lb. from the ore, *i.e.*, about 85 per cent. of the spelter came directly from ore. These are rather superior figures from the angle of metal extraction. The main drawback in this

| Ladle Skimmings | Pounds | Per Cent. ZnO | Per Cent. Metallic Zn | Per Cent. Lead |
|---|---|---|---|---|
| 1st draw | 1,165 | 42.30 | 34.0 | 0.49 |
| 2nd draw | 1,138 | 47.15 | 29.6 | 0.61 |
| 3rd draw | 1,002 | 43.66 | 25.8 | 0.99 |
| Condenser cleanings and floor sweepings | 826 | 26.75 | 32.10 | 0.87 |
| Condenser chips | 843 | 27.68 | 14.25 | 0.32 |
| Retort samplings | 4,378 | 30.29 | 14.85 | 0.61 |
| *Total* | 9,352 | | | |
| Ore charge | 19,000 | Assay 72 per cent. Zn. | | |

case is the large quantity of material that has to be rehandled. The ladle skimmings alone amount to about 17½ per cent. of the weight of the ore charge.

Another smelter (works H) reported the following:

In the regular operation of a natural gas furnace and most producer gas furnaces, the byproducts are not weighed and even if they are weighed the information is of little or no value for checking up the operation. The reason for this is that it is an easy matter for a workman to get the necessary amount of products without getting the material that is desired. The weights were obtained in the regular operation at one of the plants but even with this it will be necessary to give more or less general information as there is so much variation. On the same class of ore, however, the amount of metal that is recovered from the byproducts is rather uniform, after the method of firing the furnace, for best results, is established.

For a high-grade roasted ore containing about 70 per cent. zinc the following would be close to representative results:

Ladle skimmings, 19 per cent. of weight of ore, contents 80 per cent. zinc.

Retort samples, 9 per cent. of weight of ore, contents 35 per cent. zinc.

Condenser chips, 3 per cent. of weight of ore, contents 45 per cent. zinc.

Total byproducts, 31 per cent. of weight of ore, contents 27 per cent. zinc.

The above figures represent the byproducts from the ore plus the byproducts from retreating the original byproducts. This is the condition as it exists from day to day in the operation.

With very low-grade complex ores, the zinc contents of the byproducts is often as high as 45 per cent. of the contents of the original ore. This means that the metal recovered directly from ore to spelter is very low on these ores.

The ladle skimmings contain about 60 per cent. zinc as metallic and about 20 per cent. zinc as oxide. The lead in the ladle skimmings varies greatly, but as a general thing contains about 70 per cent. as much lead as the ore treated. If an ore is smelted which contains 10 per cent. lead, then the skimmings would contain about 7 per cent. lead.

Digitized by Google

The retort samples are much lower in lead than the skimmings, for all of the luting material goes into this product. The average is probably about 40 per cent. of the average of the ore. This product increases in lead, however, if the ore is poorly roasted. In this case there is an accumulation of lead sulfide in the mouth of the retort which is removed with the sample product.

In the above case the ladle skimmings amount to 19 per cent. of the weight of the ore charged, compared with about 17½ per cent. in works G, and their assay in zinc is very much higher. On the other hand, the amount of retort samplings is very much less. This indicates that the first of these smelters made a practice of removing a good deal more of the rich material from around the mouth of the retort. In works H, out of a total spelter production of 12,600 lb. about 3600 lb. were derived from blue powder, leaving about 9000 lb. as coming directly from the ore, wherefore about 28½ per cent. of the spelter came from the second distillation.

Improvements in methods for the minimizing of the quantity of these byproducts and for the retreatment of those that will be made inevitably is obviously a subject that deserves very careful consideration. At the present time an amount of material approximately equivalent to one-third of the ore originally charged must be rehandled and retreated, not only at direct expense, but also at the cost of the use of a corresponding amount of furnace capacity. Furthermore, about 30 per cent. of the zinc in the original ore is subjected to loss in distillation a second time, which loss in terms of percentage is undoubtedly as large as the loss in the first distillation.

In European zinc smelting practice the quantities and assays of the blue powder and other byproducts are decidedly different from the American. In one plant, excellently managed, which commonly works on a roasted blende containing 49 per cent. Zn, from which an extraction of 85 to 86 per cent. in the form of spelter is made, typical figures are the following:

| | Per Cent. of Ore Charged | Assay in Zinc Per Cent. |
|---|---|---|
| Sweeps from drawing | 15.24 | 56 |
| Condenser chips, etc | 3.77 | 60 |
| Blue powder | 3.96 | 83 |
| Total | 22.97 | |

Computation of the above figures shows that 100 lb. of ore yields about 23 lb. of byproducts containing about 14 lb. of zinc. Inasmuch as 100 lb. of ore yields finally about 42 lb. of zinc the quantity that goes first into the byproducts is about one-third of what ultimately is produced as spelter. This is not very different from American figures, but the quantity of the byproducts is less than we make, on the whole. Moreover, it is to be considered that the grade of the ore distilled in this works is lower than what we treat. It is well known that the percentage of byproducts decreases as the ore increases in grade. Thus, in treating ore of 51 per cent. grade in the same works, ladle sweeps fell to 10.33 per cent., condenser chips to 2.73 per cent. and blue powder to 2.74, a total of 15.8 per cent.

In these works the sweeps is what is obtained from the condenser and ladle in drawing. The old condensers are not only chipped, but after chipping they are crushed and concentrated over Wilfley tables. The blue powder is what is obtained from the prolongs. American zinc smelters do not use prolongs. Consequently the blue powder obtained from them and also the condenser concentrates are over and above what we get in American practice.

Considering all of these things, the European zinc distilling practice is better than the American in the matter of byproducts. This is attributable in large measure to the European type of furnace front, with the condensers enclosed in deep closets, and to the custom of drawing spelter only once in 24 hr. In works that use a small amount of salt, both in the ore charge and in skimming the ladle, there is relatively little zinc as metallics in the ladle skimmings, which is ascribed to the effect of the salt.

In reworking the byproducts some European smelters put everything in with the ore charge, but some deem it advantageous to treat them separately in a special furnace which can be operated differently from those treating an ore charge alone. The works from which I have cited figures has a plant of furnaces that are uniform in size. Five-sixths of their number are kept on ore charges and one-sixth on byproduct charges.

I am simply giving some facts in this contribution without offering any criticisms regarding any practice or expressing any opinion as to the comparative merits of American and European. Conditions are likely to determine one line of procedure in one place and another line in another place and obviously there can not be any useful analysis without a previous examination of the conditions in each case. My suggestion is limited to drawing attention to the importance of the subject.

## Eyesight Conservation in Industry

IN A careful examination of 10,000 industrial and commercial workers, active in their work and supposedly in good condition, 53 per cent. showed defective vision uncorrected. According to a booklet entitled "Eye Sight Conservation," which has been issued by the Eye Sight Conservation Council of America, employees often are accused of inefficiency and carelessness when it is entirely a matter of imperfect vision. This booklet, a part of the study of Waste in Industry conducted by the Federated American Engineering Societies, and also other literature on the subject, may be obtained from the Eye Sight Conservation Council, Times Building, New York.

# Civil Engineers' Attitude Toward Licensing Engineers*

By JOHN M. GOODELL
Civil Engineer, Montclair, N. J.

CIVIL engineers seem to number in their ranks more advocates of licensing than are found among the practitioners of other branches of the profession. Licensing was not originated by civil engineers but it was forced upon them in two ways.

In the first place, the civil engineering profession has hangers-on like every other profession. The first legislative result of their imperfect accomplishments with which I am familiar occurred in the far West. It was found that early irrigation works were so badly planned in some cases that not only were water rights made very uncertain but considerable sums were invested in structures and ditches which proved inadequate and occasionally complete failures. Water was too valuable to be wasted in that way and money too hard to obtain. In those sections, therefore, laws were passed many years ago which made it obligatory for the design of irrigation works and other structures utilizing water to be made by engineers who had satisfied a board of examiners that they possessed the technical qualifications to plan such works properly.

The basic thought on which such laws rest is the same as that on which laws governing the licensing of boiler operators rest, namely, the safety and welfare of the public. While boiler explosions still occur and irrigation works are built which are not wholly satisfactory, these laws have helped the public, it is generally agreed.

## Licensing Forced on Civil Engineers

Licensing has been forced on civil engineers in another way. A good many years ago, architects in a few sections of the country found so much unsafe and wasteful building going on under the direction of manifestly incompetent men calling themselves architects that they decided to advocate the licensing of architects. This was done first in Illinois nearly 20 years ago. The early laws were unsatisfactory to the architects and later legislation passed at their earnest solicitation was so stringent in preventing the construction of buildings from the plans of anybody who did not hold an architect's license that the engineers who made a specialty of structural engineering and the mechanical engineers who had hitherto designed the smaller structures needed in their work suddenly found themselves barred from continuing such designing. It was necessary, therefore, for the engineers to secure the passage of a law that would permit them to carry on their work after duly proving their competence in the same way that the architects were examined. This rather restricted branch of engineering, related to architecture, is made a very real danger to the civil engineering fraternity if it does not coöperate with architects who are seeking to have a law passed requiring the licensing of architects.

## Engineering Already Controlled by Law

The licensing of engineers must be considered from another viewpoint. There is no branch of the engineering profession more controlled by welfare and sumptuary laws. The architectural engineer is subject in many cities to building codes. Where there is a code and its provisions are intelligently and carefully enforced, I believe that the welfare of the public is better safeguarded than by any form of license legislation that has been proposed. Unfortunately, building codes, no matter how good, are rarely enforced and still more rarely do they apply except in large cities. Consequently there are many civil engineers who are inclined to believe that it is idle to expect real protection of the public against incompetent architectural engineering and bad contracting work through the adoption of building codes.

Again, sanitary engineers practicing in many states find that their work is controlled by regulations of the State Board of Health. In many states, any new water supply and any new sewerage system cannot be undertaken until the engineers of the State Board of Health have approved the plans. For instance, in New York and Ohio, all proposed works have their plans criticized minutely. In New Jersey, even the sizes of sewers are prescribed by regulation. In fact, sanitary engineering is so controlled by existing legislation of this kind in some states that licensing engineers cannot improve the conditions from the viewpoint of public health; but in other states, where the State Board of Health confines its attention mainly to strictly medical subjects, a great deal of sanitary engineering is being done that is very poor from an engineering point of view, and in

* Address at meeting of New York Local Section, Jan. 11, 1922.

Digitized by Google

some cases cannot be approved from the viewpoint of public health. There is a feeling among some civil engineers, therefore, that even the sanitary branch of the profession should be licensed in order to protect the public of some states against ignorance and bad judgment.

There is still another section of civil engineering work where some civil engineers believe that licensing laws may be helpful. Construction work often calls for the design of large structures, trestles, railways, falsework, reservoirs, power plants and the like. Sometimes the design of these structures used for construction purposes is more difficult than the design of the finished works themselves. Accidents due to a collapse of a bridge during construction may cost many lives. At present there is practically no legislation safeguarding workmen during construction except workmen's compensation laws. There is a feeling among some civil engineers that, if laws can be passed and properly enforced that will make it certain that temporary structures shall be designed and built only by competent men, such legislation is desirable.

### Licensing Considered Utopian

All of the arguments for licensing engineers which I have outlined are based on the assumption that it is practicable to examine engineers, register them intelligently and give them licenses that will prevent the man in the street from engaging an incompetent man for his work. The greater number of the civil engineers in responsible charge of work feel that such legislation is Utopian. It is undoubtedly their opinion that the best license law that can be written, administered with the greatest diligence and intelligence possible, can do so little toward safeguarding the public that the effort is not worth while. These men, however, are inclined to stand behind, or at least to try to guide, the movement for licensing engineers for just one reason—expediency. They feel that on account of the situation governing architectural engineering, to which I have referred, and because of the very active work carried on by a few engineers representing all branches of the profession, they must favor laws that will be fair, for otherwise unfair and unworkable legislation is probable.

I have endeavored to state the opinion of responsible civil engineers, so far as I am acquainted with it. I know of but two prominent civil engineers who believe that licensing will do any good to the profession or to the public. Unfortunately, we must also consider the opinions of engineers not in positions of responsibility, but who aspire to places of that kind and particularly to places of larger compensation without greater responsibility. There is not much danger of bad judgment on the part of the educated, ambitious, hardworking man who holds such views, which are perfectly natural, but we all realize that the man who is not particularly fitted for civil engineering responsibilities and has grown into a chronic grumbler makes a great deal of trouble at times. In the civil engineering field such men are lined up to a man behind license legislation, not because they can give any good argument for it but because they hope that somewhere from its mysterious folds it may shed a little manna into their nerveless hands. This class of engineers, who are waiting for the public to find out their merits and doing nothing to warrant attention from the public, still less its support, is far-flung and old, and years ago wearied Kipling, then a young Anglo-Indian journalist, into writing the following poem, which is inserted here as indicating the effect of the equivalent of pleas for licensing upon an intelligent young mind willing to win its own place in public esteem by hard work and study:

Study of an Elevation in Indian Ink

This ditty is a string of lies,
But—how the deuce did Gubbins rise?

Potiphar Gubbins, C. E.,
Stands at the top of the tree;
And I muse in my bed on the reasons that led
To the hoisting of Potiphar G.

Potiphar Gubbins, C. E.,
Is seven years junior to me;
Each bridge that he makes either buckles or breaks,
And his work is as rough as he.

Potiphar Gubbins, C. E.,
Is coarse as a chimpanzee;
And I can't understand why you gave him your hand,
Lovely Mehitable Lee.

Potiphar Gubbins, C. E.,
Is dear to the Powers that Be;
For they bow and they smile in an affable style
Which is seldom accorded to Me.

Potiphar Gubbins, C. E.,
Is certain as certain can be
Of a highly paid post which is claimed by a host
Of seniors—including Me.

Careless and lazy is he,
Greatly inferior to Me;
What is the spell that you manage so well,
Commonplace Potiphar G.?

Lovely Mehitable Lee,
Let me inquire of thee,
Should I have riz to where Potiphar is
Hadst thou been mated to Me?

We civil engineers believe that in view of the many laws governing the licensing of engineers which are now on the statute books, few of which have been administered long enough to give any information concerning their utility to the public or to the profession, it is desirable to exert every resource toward preventing the further passage of such laws until there has been time for more experience with those now on the statute books. I can see no reasonable defense for any more of this experimental legislation, under the claim that it is for the benefit of the safety, health and welfare of the public. Any such claim is jeopardizing the reputation of engineering for accuracy in large and small things.

Take the law of Virginia, for example, which merely says that an engineer or architect shall not call himself

Digitized by Google

a Registered Engineer or Registered Architect unless he has been licensed to do so. If he does not care to be licensed he can still offer to practice as an engineer or architect, just as he has always done. Largely through the activity of a member of the mining profession, a license law was passed lately in Arizona. Under it a barber, out of a job, can design and build a building of any kind or a power house or a dam, provided he does not claim to be an architect or an engineer.

At the other end of the long legislation scale, so full of inharmonious notes, there is the remarkable law passed last year in the state of New Jersey, so bad that no attempt has been made to administer it, so far as I can learn. An attempt was made to put a similar bill through the New York legislature about the same time, but the latter was defeated. This law, if enforced, will apparently make it illegal for the Babcock & Wilcox Co. to send one of its chemical experts from the laboratory at Bayonne to the boiler plant of any customer in the neighborhood to see what is causing, say, the pitting of the drums of a boiler bought from this company. Public welfare and business efficiency are served better than in any other way if the company's specialist in such work makes this visit and gives his advice on the case after discussing the observed facts with his associates. The company is interested, of course, in having its boilers give the very best possible service and its representative will do every thing he can to see that this service is given. On the other hand, the additional information gathered from this investigation will go to swell the total mass of information on this subject available to the company's customers throughout the country. Under this New Jersey law, it will be illegal, apparently, for an engineer of the Public Service Electric Co. to visit the plant of a consumer where trouble is being experienced with the electrical equipment of that plant. It will be illegal, apparently, for one of the engineers of the Hackensack Water Co. to talk over with an architect designing a large apartment house the proper size for the service pipes and risers.

### Undesirability of Trying to Enforce Ethics by Law

Two opinions which have been developed by a number of civil engineers who have given a large amount of attention to engineering licensing through a good many months deserve attention:

1. It is undesirable to attempt to enforce a code of ethics by means of a law requiring the licensing of engineers. As a rule, an engineering code of ethics is drawn in vague terms and is usually more applicable to those engaged in consulting work than to the greatly more numerous salaried engineers. No code proposed in the United States has been universally adopted. The time is not ripe, therefore, to word a license law, nominally passed for the public safety, health and welfare, so that it will compel every registered engineer to be a subscriber to a code of engineering ethics. That would be class legislation, which the courts will not support.

2. In the civil engineering field, most engineers work as members of organizations rather than as individuals. Even small civil engineering operations are usually best handled by a group of engineers, working with one responsible head, of course, but having an average higher responsibility than is the case in the mechanical and electrical branches with which I am familiar. Most civil engineers, in fact, do not care for individual practice of a professional nature. Some of these men associate themselves in partnerships but in recent years a constantly increasing number become associated in an incorporated manner. They are all trying to build up the reputation of the partnership or the company. That reputation is good will; it is a real asset. It is represented to the public by the firm or company name. If the owner of a silk mill in Paterson wishes to enlarge its boiler plant, he and his engineer may desire to go to the Babcock & Wilcox Co. at Bayonne for consultation about the best method of carrying out their plans, although both Mr. Babcock and Mr. Wilcox have been dead these many years. This is one case of engineering service which unwise license laws render it difficult to give.

A company was formed to carry on the work of a well known member of the American Society of Mechanical Engineers who died recently. Taking active part in the work, there are engineers, accountants, economists and a lawyer. In order to safeguard the interests of the widow of this engineer, these gentlemen asked a young banker to join with them in incorporating a company to carry on this very useful and successful practice in the best possible manner. It is being conducted by the same organization and in the same way as before the death of the founder, but in order that all interested in it may share in proper proportion its responsibilities and rewards, the organization is now that of an incorporated company. This is a desirable method of conducting the practice from every point of view, yet some forms of proposed license laws would make it illegal.

---

## Haywood Offers an Opportunity in Russia

ACCORDING to a press dispatch from Moscow, March 14, William D. Haywood heads a group of American I. W. W. men to whom Premier Lenin has granted a concession to operate the Nadezhdinsky iron works in the Urals, part of the coal mines in the Kusnetz basin, and auxiliary factories. It is stipulated that 4800 fully qualified American workers, with a technical personnel, shall be brought into Russia to operate the properties, and that each of them must purchase $100 worth of tools or instruments for his own equipment and sign an undertaking to observe all the rules of the Soviet labor code.

The announcement states that the Government has assigned $300,000 towards financing the undertaking. It is also to provide wood to build homes for workers and assign 27,000 acres of land for agriculture. The American workmen are to be organized into a trade union association.

The whole production of all these concessions is to go to the Government, which undertakes to supply the workmen with a ration and allow them part of the production as necessary means to carry on further work.

The agreement is to hold for two years. If the workmen desire to leave Russia earlier, the Government is to assist them to return to their country, after they have handed over to the state the works and factories, together with the tools, etc. brought from abroad.

# Potash Reserves in West Texas*

By DAVID WHITE

Chief Geologist, U. S. Geological Survey

THE search for potash salts in the great "Red Beds" region of the Southwest, conducted for several years by the U. S. Geological Survey, the work being carried on for a part of the time in coöperation with the Bureau of Economic Geology and Technology of the University of Texas, has resulted in the discovery, within shafting depth, of potash salts, apparently of workable thickness and commercial quality, and probably of great extent. Definite information is lacking as to the exact thickness of the potash beds, the size and boundaries of the areas underlain by workable strata, and the locations of the deposits richest and most favorably situated for exploitation.

Briefly to review the salient features of the general situation: We have in the great Red Beds region of the southwestern United States, embracing portions of central Kansas, western Oklahoma, eastern New Mexico, and northern and western Texas, a series of sandstones, shales, anhydrite beds, clays and limestones, which, through an interval of 1000 ft., more or less, carry beds of salt, estimated by Darton[1] to contain over 30,000 billions of tons of rock salt. It is the greatest known salt field of the world. At some points the intercalated beds of rock salt, one of which is reported by the driller to exceed 300 ft. in thickness, aggregate, according to the drillers' records, over 1000 ft. The sedimentary strata are similar in composition to those carrying the potash deposits of western Europe, and they were laid down at the same time and under conditions which, in many respects at least, were similar. The stratigraphy and character of the beds are described by Darton[2] and a part of the area and the reported aggregate thicknesses of salt are shown, with some revision after Darton, in the accompanying map, Fig. 1.

The assumption that in the great areas of shallow evaporation basins spread over the vast base-level region of saline deposition in the Southwest during Permo-Triassic time, potash salts were in some places, and at different stages, thrown down in crystalline deposits associated with the beds of rock salt, anhydrite, and gypsum, is, geologically speaking, more than reasonable. They are to be expected, and the conviction that they are probably present has long been held both in the Texas Bureau of Economic Geology and Technology, under Dr. J. A. Udden, and in the U. S. Geological Survey. Accordingly, for many years, efforts to determine whether potash deposits are present in this region have been made, though under very great difficulties, such as insufficient funds for boring, lack of drilling on private initiative in the more promising regions, lack of interest at first on the part of the drillers and companies, and, later, inadequacy both of the methods of boring and of the sampling, to reveal in definite terms the thickness of any saline stratum of given composition.

## First Discovery of Potash

Traces, or small showings of potash in Texas, were first discovered in 1912 by J. A. Udden[3] in the 4489-ft. hole at Spur, in Dickens County (No. 1 on map), where a brine from about 2200 ft. was found, after standing, to contain 5.4 per cent. potassium calculated as chloride. In 1915, crystals of red salt were found in material coming from between 875 and 925 ft. in the well at Boden, in western Potter County (No. 2 on map). This salt, probably polyhalite, assayed 9.2 per cent. $K_2O$.

The Miller well, bored in 1915, in western Randall County (No. 3 on map), furnished some red salt from somewhere between 1500 and 1700 ft. in depth, that contained 6.1 per cent. $K_2O$, and, at an undetermined level below 1700 ft., yielded some colorless salt particles containing 10.5 per cent. of $K_2O$.[4] The two localities last named are in the Pan-handle of Texas.

Later, in 1920 and 1921, as a result of slightly more effective watching, favored by occasional wildcatting for oil farther toward the Staked Plains, potash in the form of polyhalite ($MgSO_4 + K_2SO_4 + 2CaSO_4 + 2H_2O$), was found by the joint coöperative field agents in drill cuttings at several widely separated localities in west Texas, as follows:

1. Among some material incompletely representing irregular intervals in the Bryant well, bored by the States Oil Corpn., 9 miles south of Midland, in Midland County (No. 4 on map), were found bailings, after boring from 2405 to 2411 ft., a sample of which con-

* Published by permission of the Director of the U. S. Geological Survey.

Digitized by Google

tained 8.94 per cent. $K_2O$ in the soluble salts. The driller reported the same material to the depth of 2425 ft., but in the publication of the analysis the interval covered by the sample is erroneously given as 2405 to 2425.

2. About the same time, in the spring of 1921, cuttings bailed after boring from 1864 to 1865 ft. in the Burns well, of the La Mesa Oil Co., on the Burns ranch, 16 miles east of La Mesa, in Dawson County (No. 5 on map), were found to contain 10.82 per cent. of $K_2O$. Allowing for hangover bailings, this part of the well must be largely in polyhalite.

3. As yet the efforts to induce the companies and drillers to incur the trouble and consequent cost necessary to more frequent and careful collection of samples has been only partly successful. However, when the River well was drilled by the A. Pitts Oil Co., on the Pecos River, 8 miles east of Barstow, in Ward County (No. 6 on map), more samples were taken, though the available log kept by the driller is fragmentary and utterly inadequate. The more important results of the tests of these samples are shown in Table 1.

TABLE 1.—*Samples of Well Drillig nfrom Well of A Pitts Oil Co.**

| Depth, Feet | $K_2O$ in Sample, Per Cent. | Soluble Salts (1 Gram:100 cc. $H_2O$) | $K_2O$ in Soluble Salts, Per Cent. |
|---|---|---|---|
| 1405 | 1.68 | 87.80 | 1.91 |
| 1445–1530 | 0.74 | 87.34 | 0.85 |
| 1600–1610 | 9.03 | 62.74 | 14.40 |
| 1610–1614 | 5.60 | 66.54 | 8.42 |
| 1620–1625 | 0.77 | 93.54 | 0.82 |
| 1625–1636 | 0.48 | 94.70 | 0.51 |
| 1645 | 4.23 | 40.32 | 10.50 |
| 1660 | 0.59 | 89.64 | 0.66 |
| 1695–1700 | 6.29 | 55.42 | 11.35 |
| 1700–1704 | 2.49 | 43.46 | 5.74 |
| 1760–1770 | 0.39 | 93.44 | 0.42 |
| 1770–1780 | 0.29 | 98.10 | 0.30 |
| 1780–1785 | 0.31 | 88.34 | 0.35 |
| 1785 | 0.25 | 21.42 | 1.17 |
| 1800–1804 | 0.13 | 33.08 | 0.39 |

*8 Miles East of Barstow, Ward County, Texas, Located on Sec. 25, Blk. 33.

This well, like the others, was drilled for oil. At the depth of 2275 ft. not all the salts could have been penetrated. Crusts and lumps of polyhalite were found in the sump by the field observer. Two of these, on analysis, proved to be pure polyhalite. The salts in the pit at the time the samples were found came from the intervals between the 1000 and 1500-ft. levels. One specimen weighed slightly more than an ounce, had a fine crystalline structure, and was of a dark brick red color. The other specimen, about the same size, had a much finer texture, similar to that of the polyhalite found at Stassfurt; the color was a light red to salmon. This specimen was perfectly uniform in composition, no inclusions of any sort being visible, the surfaces showing perfectly clean fractures, and to all appearances it had been chipped from a much larger mass.

It is interesting to note, in the analyses made by George Steiger, and given in Table 2, that neither specimen contained chlorides. For comparison, analysis of a gray polyhalite from Stassfurt and the theoretical composite of polyhalite are given.

TABLE 2.—*Analysis of Two Samples of Well Drillings Compared with Two Other Analyses*

| | Red | Salmon | Stassfurt | Theoretical |
|---|---|---|---|---|

From the meager evidence at hand, it is evident that polyhalite was laid down at four or more levels in the Pitts well. It is much to be regretted that cuttings were not gathered at every 5 ft., and, still more, that cores were not cut through the saline deposits in order that indispensably necessary facts as to the thickness and purity of the polyhalite beds themselves might have been obtained when the well was drilled.

4. Information far more exact and satisfactory in character has lately been obtained at the Means No. 1 well, drilled for oil by the Pinal Dome Oil Corpn. in northeastern Loving County, Texas, a short distance west-southwest of the southeast corner of New Mexico (No. 7 on map). Fortunately, this well was bailed at every 5 ft. between 535 ft. and 4030 ft. and samples of the bailings were taken. All these have been subjected to rough tests for potash, with supplementary assays in the chemical laboratory of the U. S. Geological Survey of the samples that showed notable values in potash. These samples, which will be discussed later, reveal the presence of a dozen levels between the depth of 930 ft. and 2350 ft., at which potash occurs in unusual amounts. Five of these levels, or stages, contain salts notably high in potassium in deposits with indicated thicknesses of several feet.

5. The McDowell well, No. 4, in northern Glasscock County, next to be considered, would appear to be near the southeast margin of the main region of salt deposition and, as will be noted on the map (No. 8), is reported by the driller to have only about 190 ft. of rock salt in the aggregate through a distance of 2610 ft. The sampling of this well, which is close to oil produc-

Digitized by Google

tion, is imperfect, but there seem to be seven zones that show small amounts of potash. However, the sample from the bailings after drilling from a depth of 1035 to 1050 (15 ft.) was found, by analysis, to contain 10.67 per cent. of $K_2O$, or 15.22 per cent. of the matter soluble, 1 gm. of sample to 100 cc. of water. Allowing for "hangover" bailings from above, this locality is notable.

6. To complete the record, mention may be made of the presence of 22.9 per cent. of $K_2O$ reported in the soluble salts in a sample *selected* from the cuttings from between 1070 and 1075 ft., and of 17.68 per cent., according to the analysis, of $K_2O$ in similarly selected specimens from cuttings from 1075 to 1083 ft. in the G. A. Jones well on the Long ranch, 16 miles east of Gail, Borden County (No. 8 on map). A picked sample from bailings at 1115 ft. in this well showed 6.59 per cent. $K_2O$ in the soluble salts.

It should be explained that the assay method employed requires a quantity of water for the treatment of 1 gm. of salt capable of dissolving but 0.208 gm. of the 0.450 gm. of $CaSO_4$ contained in 1 gm. of polyhalite. By a simple calculation it will be noted that soluble salts from pure polyhalite will contain about 22.5 per cent. of $K_2O$. The sample referred to above as containing 22.9 per cent. of $K_2O$ evidently was pure polyhalite.

The Means well (No. 6 on map), in Loving County, Texas, may not lie in that part of the basin containing the thickest or richest deposits of potash in this great Red Beds region, but it furnishes the most complete and relatively succinct data obtained up to the present moment as to the vertical range and thickness of the potash zones at any point. Cable tools were used. In Fig. 2 is plotted a part of the log of the well, as reported by the driller, and opposite is shown the potash content of most of the systematic series of samples from the 5-ft. bailings, each in its relative position; *i.e.*, the graph of the $K_2O$ assay of the sample of the bailing brought out after drilling 5 ft. is opposite the same 5-ft. portion of the columnar section representing the well log. The hollow block shows the percentage of potash in the sample as taken from the bailing. The line drawn at the level of 15.6 per cent. indicates the amount of $K_2O$ that should be present if the sample were composed entirely of pure polyhalite. The solid block shows the percentage of $K_2O$ in that part of the sample that is soluble when 1 gm. of the latter is placed in 100 cc. of water.

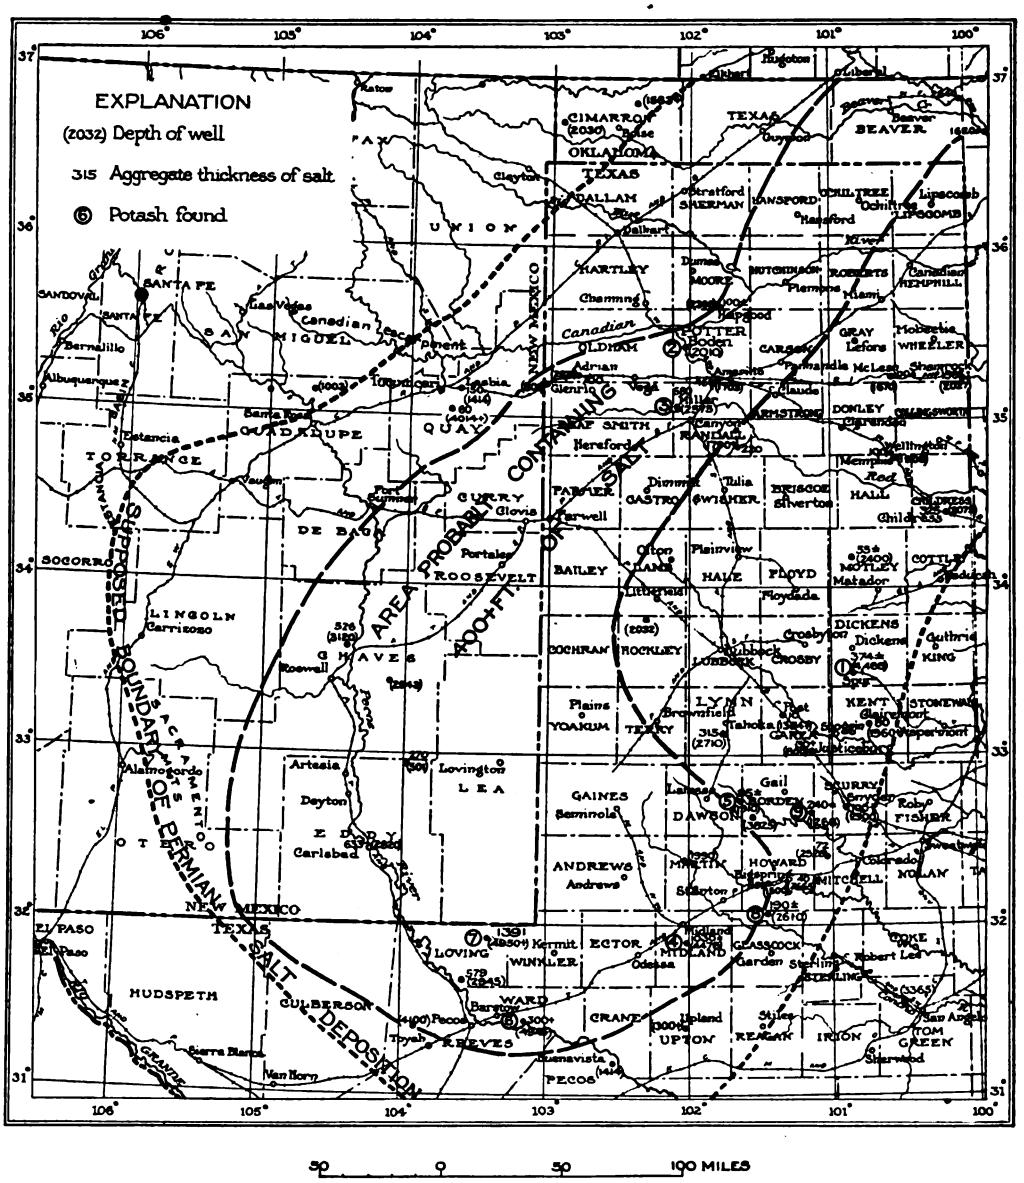

FIG. 1.—PART OF RED BEDS SALT REGION, TEXAS AND NEW MEXICO.

The graph of the potash assays of the 5-ft. cuttings from the Means well deserves study. It is evident that the bailings from the 5 ft. between the depths of 990 and 995 ft. in the well consist mostly of polyhalite. These cuttings were probably—almost certainly, in fact—diluted by rock remaining from the cuttings from the lean strata above, and some of this overhang may have been bailed at 1000 ft., where the cuttings, 995 to 1000 ft. show nearly 4 per cent. $K_2O$. We may infer, from the relative proportions of $K_2O$ in the raw

Digitized by Google

samples and in the soluble salts in the cuttings between 1235 and 1260 ft., that rock salt is intercalated; so in the zones 1575 to 1600, 1620 to 1645, and 1690 to 1700 ft. Considerable polyhalite is present with salt in the interval 1735 to 1750 ft.; but it is evident that the salts soluble, 1 gm. of rock in 100 cc. of water, in the cuttings 1815 to 1830 ft., are largely polyhalite, which, as in the interval 1735 to 1750, must compose about one-half of the cuttings brought up by the bailer. It is interesting to note the large percentage of $K_2O$ in the soluble salts between 2000 and 2010 ft. of depth in the well. The fact that this interval is recorded by the drilled as "anhydrite, etc.," though the top 5 ft. is perhaps nearly one-third polyhalite, suggests a thought as to the interpretation of the logs of other wells for the guidance of those searching for potash. Apparently the soluble salt supposed to be found between 935 and 940 ft. is likewise mostly polyhalite, though relatively small in amount.

### Value of Sample Affected in Various Ways

The exact positions and thicknesses of the polyhalite beds passed through in the Means well are debatable subjects on which drillers as well as geologists probably disagree. It seems reasonable, however, to conclude that the drill entered the potash salt very close to 990 ft., and that some hangover rock stuff from above has in effect adulterated the bailings taken from the well after drilling from 990 to 995 ft. The drill probably passed the potash bed before reaching 1000 ft. The potash bailed at the 1005-ft. level may have fallen down or, possibly, hung over from the two previous "screws." The deposits represented in the 995-ft. cuttings may be of workable thickness. The cuttings between 1820 and 1830 ft., which probably may be safely regarded as more than half polyhalite, evidently contain some salt. Probably the grade of the material between 1815 and 1820 ft. is better than indicated in the chart, since much hangover rock of low grade is presumably present.

Only those familiar with the operation of the cable drill can understand fully the possible extent to which material caving into the hole, or remaining in the hole through repeated bailings, may affect the value of the sample and so demand consideration in the interpretation of the log and samples representing any particular interval. Chemists as well as drillers may judge as to the possible exaggerations or disproportions in the assays of the solid matter in the bailings caused by the solution of the more soluble salts. This is likely to affect the results to a critical extent. This aspect of the Texas examinations has very recently been set forth clearly by George Steiger,[5] chief chemist of the U. S. Geological Survey, as follows:

> Oil being the objective and not the soluble salts, no record was kept, so far as known in the Geological Survey, of the quantity of water in the wells or the length of time it may have been in contact with the salts. Neither are any data available concerning casing used, consequently no conclusions could be drawn regarding the possible contamination due to material falling in from higher levels, and only a vague guess could be made as to what extent the potash content of the samples assayed may have been changed by the action of water. Also, it is not known whether the entire amount of material supposed to have come from the section in question had been carefully sampled or a grab-sample taken from a single bailerful.
>
> The samples as received were in fragments approximating in size cracked corn. Had water played the part of dissolving the more soluble salts, the remaining fragments would be expected to show certain characteristics. Fragments of salt only partly dissolved would probably be found with rounded edges. On the other hand, sharp edges on angular fragments might be accounted for by assuming the presence of water in volume sufficiently large to dissolve quickly all salts, including polyhalite, shortly after being torn loose by the drill.
>
> Under the latter condition, a sample would represent material through which the drill had passed immediately before bailing. Many of the samples examined contained well-rounded grains of sodium chloride, and, as might be expected, the angular structure of the fragments of polyhalite and anhydrite had been more perfectly preserved.

Only cuttings and detailed assays of cores can reveal the exact sequence, thickness, and purity of the potash beds.

The evidence appears, therefore, on the whole, strongly to indicate that we have in west Texas and probably in southeastern New Mexico workable beds of polyhalite within 1200 ft. of the surface, and extending through considerable areas. It is practically certain that in this region the United States possesses enormous reserves of potash. It remains to be learned, however, how many, how pure, and how thick the deposits may be, not only in districts as yet wholly untested, but also in the areas where, at the present moment, the information is sufficient only to prove the existence of potash, as at the Bryant well and at the localities in the Panhandle.

In Fig. 1, is reproduced, with some revision, a portion of the map compiled by Darton to show the locations of salt deposits reported by the driller, the depth of the wells, and the aggregate thicknesses of salt as logged. On it I have placed, with some revision to conform to recent studies, the boundary of the area probably containing 400 ft. or more of salt in the aggregate, and the supposed boundary of the Permian salt deposits. However, great uncertainty attends the drillers' logs, not only as to polyhalite, which, as we have already seen, may be put down as anhydrite, but even as to salt. As Darton points out, "pink and red rock," "limestone," as anhydrite is sometimes labeled, "lime shells," etc., give scant information. Some of the logs are obviously defective in their record of the salt beds, and many of the holes are not deep enough to have penetrated all the salt layers, a fact which introduces another element of uncertainty in any deduction as to the region of maximum salt deposition.

It has generally been assumed that potash, if present, would be found in the regions of greatest salt deposition. The greatest published thickness of a single salt bed is that of 380 ft. reported by Darton at Hutchinson, Kansas. The Means well, in Loving County, Texas,

[5] Potash Salts of Western Texas: *Chem. & Met. Eng.* (Jan. 25, 1922) **26**, 175-6.

Digitized by Google

revealed, according to the interpretation of the cuttings by D. D. Christner, joint coöperative field observer, and, later, by Harold W. Hoots, of the U. S. Geological Survey, three distinct beds, each having a thickness of 250 ft. or more, the uppermost being 291 ft. thick. The greatest aggregate thickness of salt reported by Darton in any well was 700 ft. at Adrian, in Oldham County, Texas, but the total of the salt in the Means well appears to be 1391 ft., the greatest aggregate thickness yet reliably recorded. Salt beds are found in this well at a depth of 990 ft. and at 4474 ft. The well is now at 4950 ft. This illustrates the fact that the recorded thicknesses of salt shown on the map depend, in many cases at least, on the depth of the hole. Potash in notable amounts was not found below 2350 ft. in the Means well, though 3 per cent. of $K_2O$ was discovered in the 5-ft. bailings for 20 ft. above that level.

Notwithstanding the presence of the three very thick beds of rock salt in the Means well, it is not yet conclusively shown, if allowance be made for depth, that this well lies in the area of maximum salt deposition. That the region is, however, one of great saline precipitation is corroboratively indicated by the record of about 1025 ft. of rock salt in the Bryant well, Midland County, Texas, which is 1478 ft. deep, and the log of 634 ft. of aggregate salt beds in the 2820-ft. well at Carlsbad, New Mexico.[6] Presumably more salt will be found at greater depth in the vicinity of this well and in the Toyah-Bell No. 2 well in southeastern Loving County, 24 miles north of Pecos, where 579 ft. of salt was penetrated before the drill stopped at 2945 feet.

If we assume that the greatest number and perhaps the thickest beds of polyhalite were deposited in the region of greatest deposition of salt, we may conclude that, so far as our knowledge goes at the present moment, the greatest reserves of potash in the southwest Red Beds region lie in the southern end of the Staked Plains country of western Texas, and southeastern New Mexico. This assumption appears reasonable, notwithstanding the fact, as reported by Darton, that no important amount of potash was found in the samples from the 2820-ft. well drilled near Carlsbad, N. Mex., in 1913, nor in the 3120-ft. hole drilled 13 miles north-northeast of Roswell. Apparently in agreement with this is the circumstance that, so far as the Geological Survey is informed, no salt seems to have been met in drilling the Walcott No. 1 well, in Martin County, Texas, about 30 miles north of Midland to a depth of 1990 ft. Digressing, it may be mentioned that this well marks a region of potash stock promotion of the most daring type. The seeming absence both of salt and of notable amounts of potash in this well may be explained by post-Permian deformation into synclinal structure, rather than as due to local conditions of deposition not yet discovered. Confirmative evidence on the latter point is much to be desired. Possibly the greatest potash deposition lies in a transverse east-west or crescentic evaporation basin.

On the other hand, it is possible that the thickest deposits of potash salt will not be found in the areas of greatest total aggregate thickness of rock salt, though the greater number of potash zones may be looked for in those areas. The richest potash deposits may have been laid down in areas of relatively complete evaporation where deposition of rock salt was not so great in total aggregate thickness, but was notably heavy in a relatively restricted period and the corresponding portion of the columnar section. The writer expects the best deposits of potash salt to be not only eccentric to the Permian salt-bearing area, but perhaps at one side of the region of actually greatest aggregate thickness of salt. As the case now stands it would appear that the best, meaning the richest and thickest, high-grade deposits, are, fortunately, in the

Digitized by Google

upper zones of those wells of which we have the most complete knowledge. Deeper drilling, or more thorough sampling, may reverse this tentative deduction. The detailed study of the logs, with correlations of horizons and strata from well to well and from outcrop to outcrop; the determination of the structural conditions obtaining at the times of evaporation of the seas, and the investigation of the physiographic and depositional history of this general region during the Permian and Triassic periods, all of which are essential to the settlement of these questions, are tasks now engaging the attention of Mr. Hoots, whose conclusions should guide the prospector to more intelligent testing for potash in the higher, the middle, or the lower zones.

From the Burns well (No. 5 on map) where 10.82 per cent. of $K_2O$ was found in the soluble salts from bailings after drilling from 1864 to 1865 ft., to the Bryant well (No. 4 on map) where the bailings, after drilling 6 ft., from 2405 to 2411, contained 8.94 per cent. of $K_2O$, is about 65 miles south by west; from the Bryant well to the River well (No. 6 on map), where potash was found at four levels and the test remains incomplete, the distance is 75 miles west-southwest; from the latter well to Means No. 1 (No. 7 on map), is 40 miles north-northwest, and from the Means well to the McDowell well No. 4 (No. 8 on map), in Glasscock County, where 10.67 per cent. of $K_2O$ has been found in bailings after drilling from 1035 to 1050 ft., is about 110 miles due eastward. The polyhalite lumps from the Jones well (No. 9 on map) must not be forgotten.

Remembering the incompleteness of the sampling and the consequently unsatisfactory status of the tests at many of the northern wells, including the Panhandle localities, it is evident that the general area embracing the discoveries of potash is enormous, being in round numbers about 275 miles long and over 125 miles wide. Between Adrian, where Darton records 700 ft. of rock salt in the aggregate and Barstow, Tex., are many counties in Texas and southeastern New Mexico, in which, as indicated on the map, there appear to have been no tests whatever. What may ultimately be found in this great area remains to be seen. In fact, the drillers have taken little interest in potash possibilities and, consistently, in preserving samples of the salines in western Oklahoma, while it can not now be confidently stated that potash is not present in the region of very thick salt deposition in Kansas, as mapped by Darton. At the present moment, however, it seems probable that the most promising region for prospecting for potash lies between the 101 and the 104 meridians, and between the 30°30′ and the 31°30′ parallels, with the indication that the salt beds thin rapidly to the southwest of the Pecos River in this region. This tentative view may be annulled by a carefully conserved set of cuttings from a single well; later exploration may locate the best deposits wholly outside of this area. These undetermined but fundamentally important points, together with such factors as transportation, water supply, and fuel, must be taken into account by him who first undertakes commercial development in west Texas or southeastern New Mexico, lest he make his investment only to find his rival developing more favorably located or far thicker deposits discovered subsequently.

Oil in small amounts has been developed in Loving, Pecos, Reeves, Glasscock, and Mitchell Counties, all within, or adjoining the region of potash prospects, and wildcatting for oil if not for potash is certain to go forward. There is hardly a possible doubt that wells for oil have been drilled through important deposits of potash salt without recognition of the latter on account of the indifference or inertia of the prospector, notwithstanding a possible far greater ultimate value of the potash. A speedy reversal of this attitude will tend to promote the interest of the operator as well as of the public.

### Commercial Possibilities of Products

Polyhalite, consisting of sulfates of potassium, calcium, and magnesium with water ($MgSO_4 + K_2SO_4 + 2CaSO_4 + 2H_2O$) is a low-grade ore of potash but is readily soluble; further, all the sulfates are beneficial to most soils, so that the rock as mined constitutes, in effect, a water-soluble fertilizer containing the equivalent of 15.6 per cent. of potash, $K_2O$, when pure. Such a rock might be used in a raw state for agricultural purposes over a considerable area, the limits of which are fixed by relative costs of mining and transportation. If the beds are as thick as is now indicated inconclusively by the cuttings, we probably have in west Texas deposits capable of supplying a large area of the western cotton region and much of the western beet sugar and fruit-growing country. Obviously, however, it is too early to speculate as to what will be the market radius of simple concentrates or of the more fully refined salts. In studying the commercial possibilities of the deposits, attention should be given not only to the geographic position of the west Texas potash with reference to the great regions of Mid-continent potash consumption and to the Lake, the Atlantic, and the Gulf ports of entry of the richer foreign salts, but also to the geographic and transportation relations of west Texas to the packing plants of Fort Worth, Kansas City, and Memphis; to the phosphates of southwestern Tennessee, and to the potential nitrates of Mussel Shoals.

A more widespread and effective fertilization of the soils of the United States is not merely an agricultural requirement, as is generally acknowledged, it is a national necessity, on which depends the commercial welfare and prosperity of our country in the future. Our position in international trade, and our national financial independence, not to say dominance, can not be sustained indefinitely by the sacrifice of our irreplaceable mineral deposits; a balance of trade in favor of this country can not always be maintained through the sacrifice of our oil, our copper, our sulfur, and other

Digitized by Google

mineral heritages in order to make good a deficit met in former years by the export of foodstuffs not needed in our own country.

The present trend of enormous increase in the consuming population which so rapidly swells our cities; of arrested growth of agricultural population and production, and of faltering, if not actually doubtful recuperation of our worn out or rapidly exhausting soils, constitute a menace to this nation of which the disastrous and far-reaching significance is not realized by a public habitually optimistic and blindly complacent. This is the most important economic problem of the United States. Beside it our war debts are trifling and ephemeral. Times have changed and are still changing. Either we must shift our economic basis back to the exportation of replaceable foodstuffs in larger amounts to maintain our trade balance or we must gravitate insensibly into the manufacture of raw materials, imported as well as domestic, on a plane of competition gradually approximating that of the Old World nations. The latter course will inevitably entail not only a continuous stern struggle for commercial prestige and independence, but a sacrifice of our standards of living as well. The productivity of American soils must be restored by every practicable means. Nothing that will lessen the cost of fertilizers or promote their wider and wiser use on our lands can be overlooked or allowed to stand in the way.

The interests of the public demand early and reliable information as to the exact thickness, extent, composition, centers of richness, availability, and possible utilization of the potash deposits in the Southwest. If these questions are not soon solved through private initiative, they should be pushed to adequate conclusion by the state or the federal government. Carefully distributed core drilling is imperatively needed.

## Corrosion Committee

THE National Research Council recently appointed a committee connected with its Division of Research Extension, with the following membership:

W. M. Corse, chairman; National Research Council, Washington D. C.

Colin G. Fink, secretary; 101 Park Avenue, New York, N. Y.

John Johnston, Yale University, New Haven, Conn.

D. M. Buck, American Tin Sheet and Tin Plate Co., Pittsburgh, Pa.

Wilder D. Bancroft, Cornell University, Ithaca, N. Y.

G. K. Burgess, Bureau of Standards, Washington, D. C.

William H. Bassett, American Brass Co., Waterbury, Conn.

E. M. Chamot, Cornell University, Ithaca, N. Y.

This committee is to serve as a general clearing-house and to devote its attention essentially to fundamental scientific study of corrosion. The committee desires to get in touch with the work that is being done on corrosion whether through societies, associations, institutes, universities or private or industrial laboratories.

A statement from Dr. Colin G. Fink, the secretary, says that the corrosion problems have been attacked from two more or less different angles. In one case every effort is being made to arrest the corrosion of the materials now in use; in the second case, new materials are substituted and tried out. There are a series of distinct corrosion problems each centered about some specific material or article of manufacture. For example, there are the problems of the corrosion of food containers and of the corrosion of buried conduits and cables. Besides these specific problems, there are the general investigations on the causes of corrosion under varying conditions and of various materials.

Within the last year decided progress has been made in cutlery steels, in metals and alloys for mine equipment, in cable sheath, in insoluble anodes and in alloys resistant to high temperatures and the corrosive action of molten metals such as zinc, tin, etc., but the corrosion problem, as a whole, in spite of its long past history, is still in its infancy and it is only through coöperative effort and a free discussion of results (those suitable for advertising purposes as well as those usually suppressed) that consistent forward strides are possible.

## International Association of Engineers

THE secretary of Engineering Foundation was the guest of honor at a dinner at the Czechoslovak Legation in Washington, Tuesday evening, Jan. 31, given by the Minister, Dr. B. Stepanek, in appreciation of some helpful services which the Foundation office had been able to perform for the Legation and through it to the engineers and University of Czechoslovakia.

There were present: Doctor Stepanek, his sister Mlle. Stepanek, Ing. Stanislav Spacek, Technical Attaché, Doctor Stangler, Commercial Attaché, Col. John Temple Graves, journalist and orator, James Milholland, journalist, and the following American engineers: Arthur P. Davis, director, U. S. Reclamation Service; Alfred D. Flinn, secretary, Engineering Foundation; George Otis Smith, director, U. S. Geological Survey; Dr. S. W. Stratton, director, U. S. Bureau of Standards; L. W. Wallace, executive secretary, Federated American Engineering Societies.

Doctor Stepanek suggested that the engineers of the world should take a leading part in the world's reconstruction, which cannot be accomplished solely by the men in political life. To be effective, the engineers of the various countries should be brought into relationships through an international association of engineers. Through this association policies could be formulated and agreed upon, information could be exchanged and

Digitized by Google

the helpful leadership of the profession constructively exercised in international as well as national movements for the good of mankind.

Doctor Stepanek mentioned the problem of Russia's reconstruction as being chiefly an engineering problem, deserving the most serious consideration of American engineers. He reminded his guests of the friendly bonds between the people of his country (Bohemia) and those of the United States, which are constantly being strengthened. He spoke also of the other fact, that his compatriots, being of Slavic race, were kindred to the Russians and might readily form a useful link for uniting the engineers of America and western Europe with those of Russia. There are 2000 Russian students in Prague.

Strong efforts are being made to transplant to Czechoslovakia (Bohemia) many of the elements of American culture, especially in scientific and technological fields. The engineers of Bohemia regard the American engineers as the leaders of the world in the profession and look to them to discharge their responsibilities for such leadership. It was suggested that a meeting of engineers for the promotion of the international association of engineers should be held in the near future in Prague, to familiarize especially the American engineers with the problems involved.

## Dilute Sulfuric Acid in the Liquid Phase

THE fact that certain copper silicates, in which the copper exists as a dilute solution of copper silicate in quartz, were less soluble in $SO_2$ than in sulfuric acid led to an investigation at the Tucson, Ariz. station of the Bureau of Mines, of the possible solvent effects of other salts in solution. It was found that iron in solution noticeably increased the formation of sulfuric acid, which aided dissolution. This suggested the possibility of utilizing the drum as a means of making dilute sulfuric acid in the liquid phase.

In the Bureau's $SO_2$-leaching drum the sulfites are almost immediately oxidized to sulfates. The oxidation of $SO_2$ to $SO_3$ is slow, even under the favorable conditions existing in the drum; iron in solution accelerates this action. The results from a series of tests using pure iron salts under conditions similar to the drum operation indicate the practicability of manufacturing $H_2SO_4$ by chemical reaction. Ferrous sulfite is oxidized by the hot air or oxygen to ferric sulfate. The ferric sulfate reacts with $SO_2$ to make sulfuric acid and ferrous sulfate. To effect the rapid oxidation of ferrous sulfate, it is necessary to get intimate contact with the air or oxygen. This can be effected by heating in the air, using high-speed agitation methods, or by passing the air through a porous medium, such as the Callow cell. The Bureau's drum is the preferred apparatus, as it effects the desired oxidation and at the same time provides for a high utilization of the $SO_2$ needed in the second stage of the reaction.

Tests completed by the Bureau of Mines to date indicate that it is practicable to manufacture 0.5 per cent. $H_2SO_4$ in the leaching pulp during a regular operation. This greatly helps the extraction of copper from the lower silicate minerals.

## Meeting and Exposition in Liége

THE papers to be presented at the meeting of the Association des Ingénieurs sortis de l'École de Liége will be grouped in seven sections: mines, metallurgy, mechanics, electricity, chemical industries, geology, and civil engineering. The mining papers, although largely on coal and oil, will deal with some subjects of general interest, such as rescue work, ground movement and subsidence and estimating ore deposits. The metallurgical papers will relate to various metals.

This Congress and Exposition have been arranged to celebrate the 75th anniversary of the Association. The Congress will be held from June 11 to 16, and the Exposition will remain open until July 14.

Tentative programs and notifications regarding fees are in the office of the secretary of the A. I. M. E., and may also be obtained by writing to the secretary of the Association des Ingénieurs sortis de l'École de Liége, 16 Quai des Etats Unis, Liége, Belgium.

## Cost of Producing Chinese Pig Iron in 1919

THE Hanyang Iron and Steel Works, Hanyang, China, draw their iron ore from their own mines at Tayeh. The cost of production at Tayeh in 1919, according to the London *Ironmonger*, was below $2.80 per ton, but the transportation to Hanyang cost $0.85, which, together with other expenses, brought the cost up to about $4 per ton at the furnaces. This cost has since been lowered by smelting the ore at Tayeh but an allowance must be made for the coke which has to be taken to Tayeh. As nearly equal quantities of coke and of ore are used in the furnaces, the saving effected in transportation is not of much significance. Limestone also comes mainly from Tayeh. The cost per ton at the Hanyang furnaces varied in 1919 between $2.32 and $3.81. These figures include all transportation and overhead charges. Manganese comes from the company's mines at Changlai and Yangshin.

**Minimum Wage.**—The "economic adviser" of a local trade union has estimated $2333 as the minimum wage necessary for a laborer to support his family in the State of New York. The *Times* compares this estimate with the revelation of the income tax returns that out of a population of 10,384,144 in the state only 742,704 reported incomes in excess of $1000 in 1920 and only 433,200 reported incomes of more than $2000.

# Experiment in Ore-hunting Geology*

By AUGUSTUS LOCKE

Mining Geologist, San Francisco, Calif.

THERE are three matters related to ore-hunting which I wish especially to discuss here: first, the paucity of the special writings applying to it; second, the failure of scientists to concern themselves importantly with it; and, third, resting on these conditions, certain possible activities for economic geologists.

First, as to the writings. Geological papers are being produced in the United States alone at the rate of 10 to 12 shelf-feet per year.[1] But papers specifically for the ore-hunter would go in a slim, annual pamphlet; all that have ever been written would go in a briefcase. The art of technical ore-hunting—geology conceived as a guide to ore—has only a scant literature.

## Amateurish Geologist's Efforts

This fact, in any thought of ore-hunting as a profession, must be deeply significant; for the very lack of a literature is no more a cause than a symptom of insufficiency. We may, indeed, assume that a store of ore-hunting technique lies hidden in the minds of commercial workers, but the scantiness of books denies it; for the nature of the art is such that its ample development, in isolation, by individuals, is incredible. The technical ore-hunter is still a beginner and the geologist in applying his skill to the search for ore is likely even to be amateurish.

For an example of what this statement means, let us watch two examinations of a leached capping area suspected of meaning copper below.

The first examination is made by a geologist, possessed of the "fine touch." The interest of this man is geology for itself, geology as earth-science; it will be a miracle, therefore, if he so change his habits on the instant, we might say, as to concentrate wisely on this particular, commercial problem. And, even should he so concentrate, what would it avail him? He can comb the literature without finding a technique to judge this capping by. Nor can he stop to develop it himself. For his employers sit waiting; they need information both cheaply gained and quickly rendered, and, rather than pause a year for their man to develop a means of judgment, they would sink a shaft. The geologist, then, must either resign the job or turn in an opinion technically unworthy.

The second examination is made by an engineer of the well known effective sort—a good business man, understanding well the requirements of size and grade for a commercial development. This engineer makes few subtle distinctions of geology; for him the capping will be difficult indeed to read; but a conclusion is necessary, and he must, therefore, take refuge in his habit of firm decision—he must take refuge in those rule-of-thumb methods which have been found in the business of prospecting to be effective.

But this is not technical ore-hunting. It is, rather, the rough and ready, common-sense method of the prospector applied under the most intelligent auspices. It is the method which still dominates in the search for new ore. It serves now; but its results are like a bridge built without calculation, strong enough to bear the traffic; or like the early automobiles, of disproportioned members and costlier in fifty places than they need be. The method finds commercial ore; but it does so at the price of many a mile of cross-cut in hopeless ground.

## Failure of Scientist to Pursue Ore-hunting

This brings us to the second heading which I outlined in the beginning, the failure of the scientist to concern himself importantly with ore-hunting.

This failure is implied in the scantiness of the literature, and it is involved, I believe, in the necessity for the scientist, if he is to go into ore-hunting, to change his viewpoint; for the scientist and the ore-hunter, have, to begin with, a difference of viewpoint that is vital.[2] One is concerned with geology as earth science; the other with geology as a guide to ore. The first has a tone of grandeur; his interests reach wide—they may even touch the stars. The second has a tone of shrill concentration; the finding of ore is the very focus of his thoughts and he will reach out for wider matters only as they affect that one. His art is

* Paper read at a joint meeting of the American Institute of Mining and Metallurgical Engineers and the Society of Economic Geologists, Sept. 14, 1921, at Wilkes-Barre, Pa.

[1] See "Geology and Geography in the United States" by Edward B. Mathews and Homer P. Little, Article No. 17 of Reprint and Circular Series of the National Research Council.

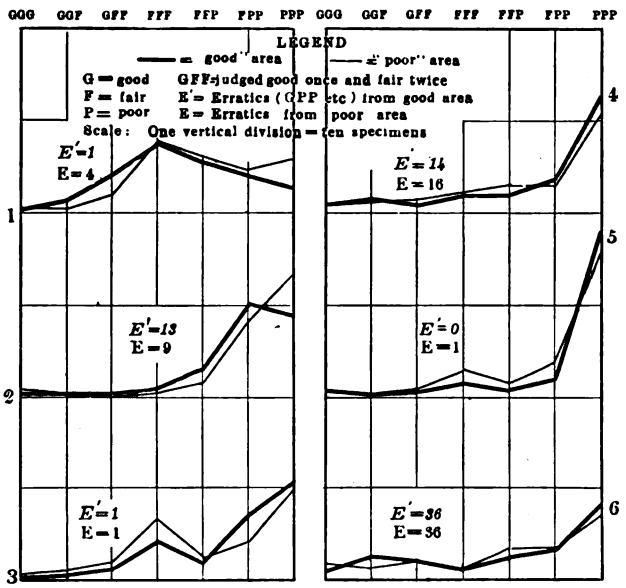
[2] Max Eastman says that a crowd swarming into a ferry boat will divide itself, part going below to smoke and read the paper, and part going to the upper deck to see what is going by: the deckriders are interested in crossing the river; the smokers are interested in getting across. These two attitudes illustrate the difference here discussed.

Digitized by Google

confined to a smaller and more specific geology; it must select for its principal work matters which seem like mere incidents in the larger scheme; and it must be verifiable in detail.

In order to show the process of starting at the necessity and building from that outward, I shall now describe an ore-hunting experiment. This experiment was aimed to determine the degree of doubt in a judgment by six men of two areas of leached cropping over disseminated sulfide stuff. The experiment was as follows:

In one of the Southwestern mining districts, two areas were selected, measuring slightly over 400 by 800 ft., the first over a body of developed ore and the second over material proved by drill holes to be hopelessly low



CURVES EXPRESSING RESULTS OF STUDIES ON TWO LOTS OF DISSEMINATED CROPPINGS SPECIMENS, ONE LOT FROM AREA 400 FT. BY 800 FT. OVER ORE AND ONE FROM SIMILAR AREA OVER WASTE. THERE WERE THREE JUDGMENTS BY EACH OF SIX MEN.

grade and pyritic. The areas yielded about 500 hand specimens taken from the centers of 40-ft. squares. These specimens, numbered according to a key, were thrown into a single heap.

The problem set was for six geologists each to sort the 500 specimens into three groups, good, fair, and poor; good meaning that the specimen came from enriched ore, fair that it came from ore of doubtful grade, and poor that it came from waste.

This sorting was done three times by each man. In addition, 25 specimens were judged with especial care and the detailed basis of judgment was written down. Throughout, such arrangements were made that no particular judgment of a specimen could be influenced by any other, either by the same man or by another.

The task took many hours of work for each man, and before it was finished it developed certain curious aspects. It showed, for example, that so delicate is the balance of judgment that even such a factor as the cloudiness or clearness of the day will influence opinion; and it indicated strange differences among the several men in the basis of judgment. One considered as favorable the tiny pits and gashes made by the departure of sulfide; for, he said, had that sulfide been other than chalcocite, it would have left limonite behind. Another, with equal assurance, regarded the pits and gashes as unfavorable; they meant abundant pyrite; for this, oxidizing, would create so strongly acid a solution as to prevent the precipitation of limonite.

The basis of judgment was proved, at least in some men, to be something felt rather than something known. Despite the experience of all these men in judging disseminated capping, their foundation, at least in part, was grossly unscientific.

Another surprising matter was the inability of certain men to maintain a standard. When, say, specimen 15 was judged by a particular geologist poor twice and fair once, that was considered satisfactorily consistent; but if it was judged good once, fair once, and poor once, by the same man, or good once and poor twice, that specimen was called erratic, for something was clearly the matter.

Among the six men, one had 72 erratics, another 30, another 22, another five, another two, and another only one. This last result was astonishing; it meant that one man so sternly maintained his standard that he was able to go through 500 specimens three times, and classify only one of them erratically. Half a dozen or a dozen erratics seemed a reasonable number.

The results from each man were platted in a pair of curves, one representing the area over ore and the other the area over waste; and, in order that the results of three judgments might be put in a single curve, the individual specimens were classified as follows:

(1) Judged good three times.
(2) Judged good twice, fair once.
(3) Judged good once, fair twice.
(4) Judged fair three times.
(5) Judged fair twice, poor once.
(6) Judged fair once, poor twice.
(7) Judged poor three times.

The pairs of curves are shown in the accompanying figure. The reader will note that, of these pairs, three express a preference for the poor area, two for the good area, and one is non-committal. Had these men been forced, on the basis of these specimens, to choose one of these areas for drilling, three would have put the holes in the poor area, two in the good area, and one would have been unable to decide.

No geologist, however, would have undertaken, on the basis of these specimens alone, to make a decision, for there are too many obvious difficulties in using 500 hand specimens as a sample of 16 acres of capping. It would be necessary, before putting any reliance on these specimens, to check them by a parallel set taken with the squares moved over a few feet; and the

Digitized by Google

probability is that several thousand instead of several hundred would be a necessary minimum to constitute a fair sample.

The important matter is not the choice between the areas. Rather, it is the definition of the degree of doubt. This particular place was chosen, I may say, because it was especially pyritic for an enriched disseminated deposit, and because it was therefore especially difficult. The establishment, among the several men, of the fact that the standards differ and that at least some of these men so far as this district is concerned have no solid basis of opinion, is the important matter, and the experiment suggests a score of directions for its amplification and refinement.

In the croppings problem of this particular district, and of disseminated copper districts in general, the scientist has shown but moderate interest. To carry the general problem through to a conclusion would cost perhaps a hundred thousand dollars and would take several years of time by research geologists of the highest grade. I wish to emphasize my belief that it is a thoroughly worthy activity for men who now devote themselves to geology as earth science. The existence of the commercial aim involves no necessary lowering of ideals. And, if "the test of theory is prophecy," then may not this specific test of prophesying ore, with its rigid compulsion of accuracy, even work a benefit to the larger geology itself?

### Definition of Special Ore-hunting Problems Desirable

To come to the third part of the outline given early in this paper—what might be the possible activities of this Society in regard to the conditions above discussed?

The outstanding activity that I wish to suggest is the definition of special ore-hunting problems—problems whose attack would help to build an ore-hunting technology. It is true that some geologists are doubtful if such problems exist—and it is true, furthermore, that the search for ore is now conducted as though they did not exist—but it would seem a proper business for the Society to combat this attitude by lively preparations for broad commercial research. This is the very moment for the application of the finer technical methods, and we may hope, till metals become transmutable, that the ore-hunting art, constantly improving, will bring us more and more swiftly toward results useful in terms of human life.

## Accident Rates for Mineral Industries

ACCORDING to data of the comparative accident rates for all divisions of the mineral industries compiled by the United States Bureau of Mines for the year 1920, the lowest fatality rate was for sandstone and bluestone quarries. These employ a relatively small number of men and all work is done in daylight, free from many dangers that are inherent in underground mining. For the same year, the highest fatality rate was that for gold, silver, and miscellaneous metal mines, a group that includes all metal mines except those producing copper and iron and those in the Mississippi Valley that produce lead and zinc.

No reports of nonfatal accidents at coal mines are received by the Bureau of Mines, but for all other branches of the mineral industry the highest injury rate was that for the lead and zinc mines of the Mississippi Valley, while the lowest was that for marble quarries.

Since the enactment of compensation laws by nearly all of the states, increased importance attaches to the accuracy and completeness of the statistical publications on industrial accidents. The insurance premiums that operators of metallurgical plants, mines, and quarries have to pay are determined largely from a study of statistical reports relating to accidents in these industries. It is highly advisable, therefore, that full and accurate data concerning accidents be reported promptly by operators, not only to aid in the study and prevention of such accidents, but also to assist state compensation commissions and other insurance bodies in establishing premium rates that will be fair and equitable.

As the practical usefulness of statistical reports are increased or diminished by the promptness or tardiness with which the figures are published, the Bureau of Mines hopes that its annual inquiries relating to accidents may be filled out by all operators and returned promptly, in order that the value of the reports of the bureau on this subject may not be diminished by any unnecessary delay in their publication.

## Coming Meetings of Societies

| Organization | Place | Date |
|---|---|---|
| Amer. Chem. Soc | Birmingham, Ala. | April |
| Amer. Welding Soc | New York, N. Y. | April 27 |
| Amer. Electrochem. Soc | Baltimore, Md. | Apr. 27–29 |
| Public Conference on Commercial Engineering | Pittsburgh, Pa. | May 1–2 |
| Iron & Steel Inst | London, England | May 4–5 |
| Amer. Zinc Inst | St. Louis, Mo. | May 8–9 |

# Government Action of Interest to Engineers

## Extracts from Weekly Bulletin Issued by American Engineering Council

MARCH 16, 1922

**Patent Office Reorganization Bill.**—The appropriation necessary to carry into effect the recent law authorizing the reorganization of the Patent Office was assured when the Senate and the House of Representatives approved the conference report on the Deficiency Bill which carries $158,000 for the Patent Office. The reorganization scheme necessarily must be put into effect gradually. Due to the heavy accumulation of applications it will require, even with an additional personnel, many months before applications can be assured of immediate handling.

**Trade Associations Conference.**—The purpose of this conference, to be held in Washington in April, will be to secure a list of trade associations, provide for furnishing statistical information suggested by the Department of Commerce, discussion of means and methods for collecting and distributing this information.

**Metric System Bill.**—Hearings have been closed on the Britton-Ladd Metric System Bill and the McNary sub-committee of the Senate Committee on Manufactures is considering a report which it will make to the full committee. "An American Decimal System of Weights and Measures" is the title of a leaflet covering a statement recently made by Samuel Russell before the Senate Committee on Manufactures.

**Chemical Warfare Service.**—Anticipating greatly reduced activities on the part of the Chemical Warfare Service as a result of the new treaty, the Committee on Appropriations of the House has cut the funds to be available to the Chemical Warfare Service during the next fiscal year from $1,500,000 to $500,000.

**Consolidation of Railroads** into a limited number of systems will be the subject of a hearing to begin on April 24 before the Interstate Commerce Commission under the leadership of Commissioner Hall. The first sessions will be devoted to roads in the southeastern region. This is the first action in this matter by the Commission since the adoption of the general plan last August.

**Alaska Investigation by the Department of Commerce.**—Assistant Secretary C. H. Huston will conduct an investigation this summer, to determine ways in which the Coast and Geodetic Survey, the Lighthouse Service, the Steamboat Inspection Service and the Bureau of Fisheries can assist in developing the territory.

**Analysis of the Coal Situation** has been issued by the Coal Bureau of the National Resources Department of the U. S. Chamber of Commerce, for the purpose of giving business men information regarding possible fuel supplies in the event of a strike by the miners on Apr. 1. The bulletin carries charts, covering conditions in various localities in the United States, and explains factors that will control supplies.

MARCH 9, 1922

**President's Conference on Unemployment.**—The Committee on Civic and Emergency Measures has issued from the Department of Commerce a compilation of the articles written on this conference under such titles as "Hoover on Unemployment," "Work for a Restless World," "Keeping Them on the Pay Roll," "Ten Helps for Slack Job Periods," etc.

MARCH 3, 1922

**Hudson River Tunnel and Unemployment.**—Chief engineer of the new Hudson River tunnel notified representatives of the President's Conference on Unemployment that the contract for construction of the subaqueous portion of the great sub-roadway would be awarded during the week of March 6, by the two State Commissions and will give work to thousands of men for several years to come, as well as indirectly aiding unemployment through the states.

FEBRUARY 23, 1922

**Cyclical Depressions.**—A conference was held at the Department of Commerce under the auspices of the Unemployment Conference on Feb. 20 to consider plans for investigating cyclical depressions. The standing committee of the Unemployment Conference has secured sufficient funds to make a quick intensive study to extend over a period of six months. Mr. Hoover made a short address and actively participated in the conference, which was attended by representatives of many important organizations. By request of the chairman of the Conference, the executive secretary of the Federated American Engineering Societies outlined suggestions for some phases of the course of procedure. The American Engineering Council at its meeting in January accepted Mr. Hoover's invitation to take part in this investigation.

Digitized by Google

**Topographic Mapping.**—The Senate Appropriations Committee has reported the Department of the Interior bill to the Senate carrying $400,000 for topographic survey work. This is an increase of $125,000 over the amount carried in the same bill when it passed the House last week.

**Patent Convention with Germany.**—The Senate adopted the following resolution on Feb. 22, which will have the approval of the President: WHEREAS under the treaty concluded between the United States and Germany, signed on Aug. 25, 1921, to restore friendly relations between the two nations the right is secured to the United States to revive, by giving notice to Germany, any treaty or convention in force between the two nations prior to the outbreak of war: BE IT RESOLVED (two-thirds of the Senators present concurring therein): That the Senate advise and consent to the giving of notice by the President to revive the patent convention concluded on Feb. 23, 1909, between the United States and the German Empire.

---

## Investigations by the Bureau of Mines*

**Storing Carbide with Explosives** (Serial No. 2280). By Charles E. Munroe.—This paper indicates a variety of ways in which accidental ignitions or explosions may occur with commercial calcium carbide. It shows that it is unsafe to store carbide in the same magazine with explosives or in close proximity to them, and, moreover, that such storage violates a fundamental rule of practice governing explosives magazines.

**Dust Reduction by Wet Stopers** (Serial No. 2291). By D. Harrington.—In the study of miner's consumption it has been found that dry drilling, especially in unventilated places, is by far the most dangerous underground occupation. The introduction of machines with water injection through the drill for cross cutting and driving readily controls the dust menace for practically horizontal holes or those with a downward inclination. This paper gives data on air dustiness with various kinds of drilling in two mining regions, and concludes that water stopers are greatly to be preferred to dry stopers.

**Present Status of Coal Carbonization at Low Temperatures** (Serial No. 2292). By Joseph D. Davis.—For 20 years an enormous amount of experimental work has been done in this country and in Europe on the carbonization of coal at low temperatures. Most of this work has been carried out on a laboratory scale, or at least on a semi-commercial scale, and only recently have results been obtained that can be used directly by the carbonization engineer. One object in view has been to learn from a purely scientific standpoint more of the composition of coal and its thermal decomposition. Another object has been the discovery and commercial development of more economical methods for processing fuels than the well-known high-temperature methods. This paper, which was presented at a meeting of the American Gas Association, Nov. 9, 1921, in Chicago, deals more particularly with the latter phase of the work.

**Precautions to be Observed in Entering Abandoned Exploratory Shafts and Pits** (Serial No. 2295). By Byron O. Pickard.—The Berkeley safety station of the U. S. Bureau of Mines was recently informed that a geologist was killed through entering an abandoned 90-ft. exploratory shaft without making a preliminary test of the shaft atmosphere. This is the second recent accident in abandoned workings.

The simple precautions in this paper are probably known to every experienced miner, but evidently are not always practiced, and the writer feels that certain publicity to common sense practices is warranted.

**Underground Loading Devices in Metal Mines** (Serial No. 2300). By C. Lorimer Colburn.—During the period of the war and immediately thereafter development of the use of underground loading devices made most rapid progress. The mining engineers of the U. S. Bureau of Mines in every section of the country have secured, with the coöperation of the mine operators, data on the actual performance of the mechanical shovels in their districts, and have made them available to the author of this paper. No effort has been made to discuss exhaustively the subject of underground loading devices. The object has been to collect in one paper records of the performance of all machines now in actual use. Nine machines are described, also slushers and drag scrapers.

**Methane in California Gold Mines** (Serial No. 2303). By Byron O. Pickard and E. D. Gardner.—Out of five California gold mines in which the air was sampled, three showed accumulations of methane great enough to be ignited. Methane has been reported in a fourth mine.

It is concluded, from the study in California, that methane is given off from certain carbonaceous rocks which are associated with many of the California mineral deposits; also that methane may be given off from timbers decomposing under water. It is believed, therefore, that any operator who has any of the above conditions in his mine should give serious thought to mechanical ventilation and properly controlled air currents in his workings.

**Fighting a Mine Fire With its Own Gases** (Serial No. 2325). By C. A. Allen, and A. C. Watts.—In the No. 3 Sunnyside mine of the Utah Fuel Co. a disastrous fire started on the afternoon of Aug. 17, 1920, the effects of which are still present in the mine. This paper is a summary of a more complete report, prepared by the writers, which will be published by the U. S. Bureau of Mines.

# Correspondence and Discussion

## Evolution of Mechanical Roasting

IN THE December issue of MINING AND METALLURGY, I have read with pleasure A. S. Dwight's very interesting paper on this subject. I appreciate his kindly reference to my furnace. He speaks of knowing it as being used only in Butte. As a matter of fact, about forty furnaces were erected, although, as most of them were somewhat changed in design by the E. P. Allis Co., which furnished the steel work for them, they were perhaps better known as the Holthoff-Wethey furnace.

In June, 1888, when I was put in charge of the Butte Reduction Works, we had only two hand rabbling brick calcining furnaces. They had a capacity of eight tons each per day of 24 hr., and were fired with wood that cost $5 per cord. The men were paid $3.50 per shift of 12 hr. The ore was roasted from 38 per cent. sulfur down to 5½ per cent. The cost per ton was $3.50. In 1889, we put in a small Bruckner cylinder having a capacity of seven tons to the charge, and in 1891 a second but larger Bruckner capable of holding 14 tons.

The old practice was to discharge the hot calcines into pits and turn water from a hose on them before throwing them by hand into the reverberatory furnace. I made several tests of the effect of cooling the calcined material in this manner, and found that it caused a large percentage of loss in copper and silver and of course kept down the capacity of the smelting furnaces. The cost of calcining ore in the Bruckner cylinders was $2.35 per ton.

In 1893, after seeing the Cole-Keller furnace in operation at the Parrot smelter, and the Pearce furnace at the Colorado smelter, I concluded that neither one of them would meet our conditions. At that time the Pearce was a single-deck furnace. I considered the Parrot furnace too clumsy and involving too much complicated mechanism. I desired a furnace having the most simple form of mechanism, and the greatest capacity possible in a given space, for we were restricted both in area and height. These requirements led to my designing a furnace best calculated to meet these conditions.

The first furnace occupied part of the space previously occupied by a hand-roasting furnace, and a Bruckner cylinder, and started in operation in September, 1894. It was arranged to deliver the hot calcined material to the reverberatory furnaces, and greatly increased their capacity, as the hot material dropped through holes in the roof of the furnace instead of being thrown in by hand through side doors.

The first furnace proving satisfactory, three others were built, and in 1904 the four furnaces[1] averaged 266 tons daily for the entire year. The cost of calcining had been reduced to about 35 cents per ton. About 4 per cent. of Rock Spring slack coal was used per ton of concentrates and slimes. The men were paid $3.50 for an 8-hr. shift, instead of the old 12-hr. shift. The costs, too, were figured on the dry weight, and as the percentage of moisture was very much greater than in the early years when much screenings from coarse ore was used, instead of the wet slimes we afterwards had to treat, the saving in cost was really greater than the bare figures actually show.

Inventing a furnace brought in a train of litigation. Cole-Keller and Gaylord claimed that my furnace was an infringement of theirs. I settled this by buying Cole's interest in that furnace. Horace Brown, who owned the O'Hara patents, claimed that both the Cole K-G furnace and mine were infringements on his. After much litigation, and getting a favorable decision in the federal court at Seattle, I settled with Brown by turning over my patents to him, retaining all royalty on furnaces already sold, and securing the right to all purchasers of my furnaces to continue their use without interference of any kind. I was the more ready to do this as I realised that this type of furnace was getting out of date, being inferior to such furnaces as the improved Pearce, McDougall and Wedge furnaces.

A. H. WETHEY.

PARIS, Jan. 2, 1922.

---

**Permissible Carbon Monoxide Indicators.**—Schedule 18, issued by the United States Bureau of Mines, gives the procedure for establishing a list of permissible carbon monoxide indicators that are light in weight and portable for quickly and easily showing presence of carbon monoxide gas in mine rescue and recovery operations; or around blast furnaces, producer-gas and water-gas plants, and metallurgical and chemical plants. Examinations and tests of carbon monoxide indicators submitted by manufacturers will be made at the Experiment Station of the Bureau of Mines at Pittsburgh, Pa. Copies of Schedule 18 may be obtained from the Bureau of Mines, Washington, D. C.

[1] Occupying the same space formerly occupied by the two old furnaces and two Bruckner cylinders.

## Testing Artillery Cartridge Cases*

BY J. BURNS READ, GOLDEN, COLO., AND S. TOUR, NEW YORK, N. Y.

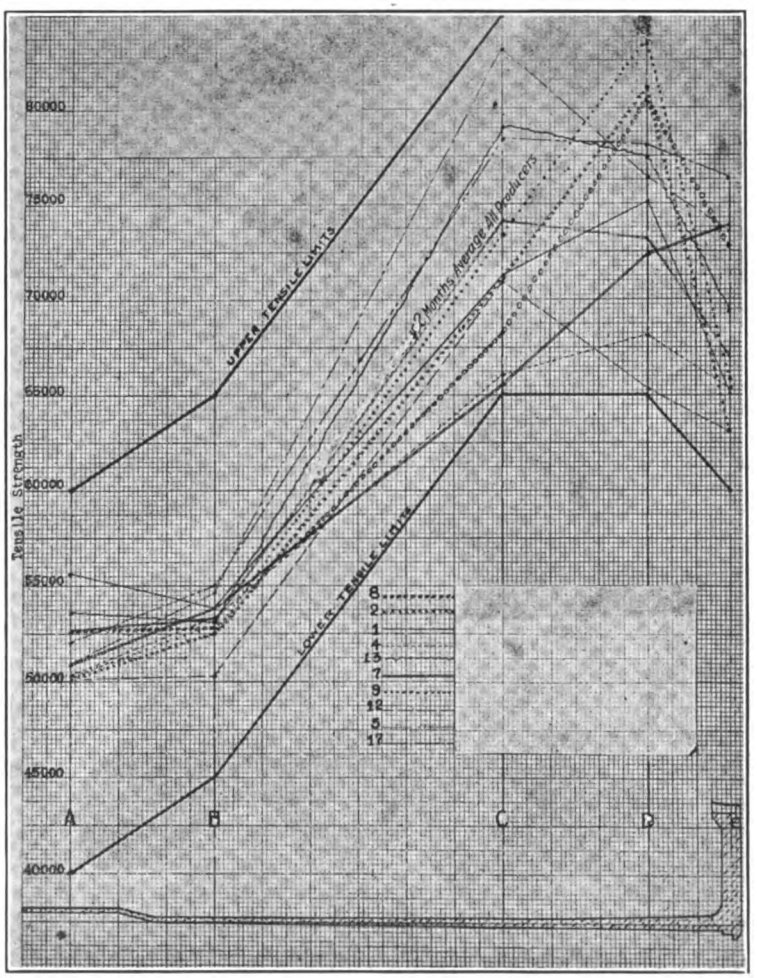
IT IS the purpose of this paper to summarize, as far as possible, the metallurgical information and experience gained by the Ordnance Department, during the war, in the manufacture of artillery cartridge cases, to describe the tests to which artillery cartridge cases were put, and to summarize the knowledge and experience gained in this testing.

Artillery cartridge cases are cold drawn from circular disks punched from strips of rolled brass. The manufacture involves from 25 to 30 main operations, which are done almost entirely on a punch press. After each cupping, or drawing, operation, except the last, the cases are annealed at from 540° to 650° C., to remove all the hardening strains set up in the metal and to allow complete recrystallization. After each annealing, the cases are pickled in nitercake or sulfuric-acid solution and then washed in water to remove all traces of acid. In some instances, the cases are then immersed in a cyanide-salt solution, and afterwards rinsed in water, to remove the thin layer of copper that forms on the surface of the cases during the acid pickle.

The last cold-drawing operation is followed by the heading operation which, by flattening the head of the case on the outside, causes the metal to flow on the inside to approximately the proper finished dimensions. The mouth, or open end, is then annealed at 430° to 480° C. by immersion in a salt bath or by gas flames. After being washed, the cases are tapered, when they are ready for machining, inspection, and testing.

Good disks of proper composition and physical properties are essential to the production of good cartridge cases. The Ordnance Department has specified the following chemical composition: copper, 68 to 71 per cent. and zinc, 29 to 32 per cent. It requests that copper plus zinc, minimum, equal 99.88 per cent.; lead, maximum, equal 0.07 per cent.; iron, maximum, 0.05 per cent.; tin, antimony, bismuth, cadmium, or arsenic, none or only a trace. The materials used are prime lake or best electrolytic copper and grade A zinc.

The specifications do not give physical properties



COMPARATIVE TENSILE STRENGTH TESTS OF TYPICAL 75-MM. CARTRIDGE CASES FROM DIFFERENT MANUFACTURERS.

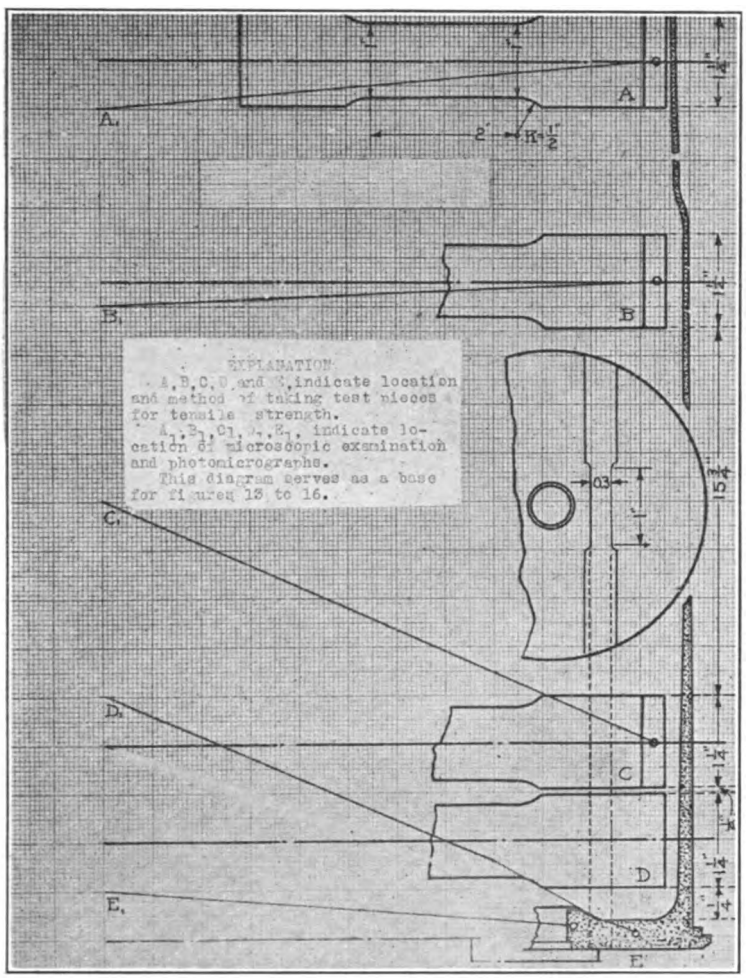
but suggest that, "An average of ten readings should be between 50 and 65 Brinell and no individual test should be below 49 or above 69." A very soft or a very hard disk has a tendency to punch through instead of cupping. The harder the disk, the greater is the strain on the press forming it into a cup, but it is generally believed that the harder disk will form a better case than a soft

*New York Meeting, February, 1921. Publication delayed by arrangement with Institute of Metals Division.

Digitized by Google

disk. Whether this is true will depend on the conditions of working and annealing in the process of manufacture. If these conditions are properly controlled, very soft and very hard disks will form equally good cases.

The testing of cartridge cases for acceptance may be divided into five sections: chemical analysis, determination of tensile strength and percentage of elongation, microscopic and macroscopic examination, mercuric-chloride test, and ballistic, or proof test. The testing by chemical analysis will not be discussed here.



EXPLANATION
A, B, C, D and E, indicate location and method of taking test pieces for tensile strength.
A1, B1, C1, D1, E1, indicate location of microscopic examination and photomicrographs.
This diagram serves as a base for figures 13 to 16.

METHOD OF TAKING TESTS OF 3-IN., 15-PDR., ANTIAIRCRAFT CASES.

During the recent emergency, the metallurgists of the Ordnance Department based their work on artillery cartridge cases on the idea that starting with a disk made of high-grade cartridge brass that had passed a thorough visual inspection, with a well-ordered shop practice covering thorough control of annealing and amount of draft, the finished case is bound to meet all requirements specified by laboratory tests, and gun-proof, in so far as the material is concerned.

Up to the time the United States entered the war, little attention had been given to the metal quality of cartridge cases. Specifications mentioned metal conditions and placed no limits other than chemical. Little systematic consideration had been given to the possibilities of control of the final product by the control of manufacturing processes. Because of many changes resulting from quantity manufacture and an increased knowledge of the requirements of cartridge cases, it was necessary to revise these specifications. The revision requires photomicrographs if the microscopic examination continues to reveal an unsatisfactory condition of the crystallized structure in several lots. This would indicate that photomicrographs, when the metal is good, were not to be taken.

The revision also provides for tensile and mercuric-corrosion tests "merely for the guidance and general information for the manufacture, and no lots will be rejected if cases fail to pass these tests." It retained the requirements of the previous specifications as to ballistic tests and storage. In order to provide for the proper application of these general specifications, from time to time instructions were issued to inspectors directing, in detail, methods of inspection and test.

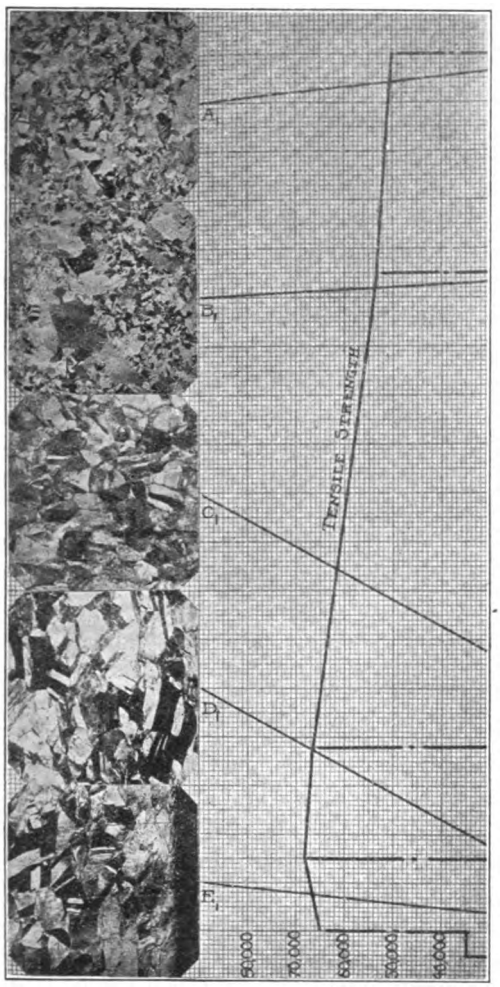
One of the first instructions directed that microscopic examinations include the making of photomicrographs. These instructions required that photomicrographs of six sections be made from each of five cases taken at random from every lot. It was then thought that the photomicrographs would furnish sufficient information for proper control of the inspection. This did not prove to be the case because of the many variables in worked brass that has not been annealed. Inexperienced personnel, varying processes of manufacture, and varying laboratory methods added to these variables and the photomicrographs did not reveal the quality of the case which they represented.

Later instructions provided optional methods of testing each lot as follows: Mercuric test of one case and microscopic examination and photomicrographs of this case and five others, six in all being required; or, tensile-strength and elongation tests of two cases, mercuric test of one case, microscopic examinations and micrographs of one case, four cases in all being required. Samples of the product of several contractors were sent to the Bureau of Standards for mercuric-test study and tensile-strength tests; the results showed that these tests were a proper means of inspection. Under either method of testing, a failure of a case to stand the mercuric test and retest constituted a rejection of the lot it represented. At first most, and later all, of the contractors adopted the second method of testing. Final acceptance or rejection, of course, is based on the results of the ballistic test.

The physical and microscopic properties of the metal of cartridge cases are largely dependent on the combined control of the various annealings and redraws, particularly the last. An increase in the amount of work done on the metal in any step reduces the tem-

Digitized by Google

perature at which the anneal of that metal will take place, and vice versa. Therefore, as the work affects the results of the anneal, the anneal affects the results of the work and both affect the physical properties. It is essential that these be considered together.



STRUCTURE AND TENSILE STRENGTH OF 75-MM. CASE AS MADE BY MANUFACTURER NO. 12.

## CONCLUSIONS

1. Tensile-strength requirements are now sufficiently established by the experience during the war to warrant their being placed in specifications and used in deciding the acceptance or rejection of cases.

2. The mercuric test has been met by reliable manufacturers, is a good test for control of the manufacturing process, is a sure indication of the behavior of the case in storage, and indicates a metal condition that cannot be detected by chemical, physical, or microscopic tests. It should, therefore, be made a definite requirement in the specifications for cartridge cases.

3. Microscopic examination should be made of a portion of the cases submitted for tensile-strength tests, also of samples of all questionable material. Photomicrographs are essential as a record and for purposes of comparison; their number will depend on conditions.

4. Ballistic tests alone are not a sufficient or proper test of cartridge cases. Except on material that is questionable, metallurgical tests taken with proper dimensions and visual inspection are sufficient and more reliable than ballistic tests.

5. The present requirements and specifications for cartridge-case disks are satisfactory.

6. Indications are that hardness tests, made by the Baby Brinell machine without cutting up the cartridge case, might be substituted for the tensile-strength test. Such tests would increase the sample, decrease the work, and save the case.

7. The low-temperature anneal (below recrystallization temperatures) seems so certain of overcoming all season cracking that its employment in the manufacturing of cartridges should be seriously considered.

8. More judgment should be used in rejecting cartridge cases because of slight visual defects.

---

# Present Conditions in Mexican Oil Fields and an Outlook Into the Future*

BY VALENTIN R. GARFIAS, NEW YORK, N. Y.

THE various phases of the Mexican oil industry have received so much publicity that there is little to add to the discussion of present and future production, extent and importance of prospective fields, and status of petroleum legislation, to mention but a few of the angles of the Mexican oil problem. However, out of this wealth of information, which is generally of contradictory nature, the average petroleum man is at a loss to know something definite regarding the various questions involved, so, keeping the foregoing in mind, it has been the writer's aim to record in a concise form the most reliable and up-to-date information regarding the salient features of the Mexican oil situation.

## PRESENT STATUS OF MEXICAN OIL INDUSTRY

The Mexican oil fields, during 1921, produced in round numbers 203,000,000 bbl. of which 176,000,000 bbl., or 86 per cent., were exported, the bulk of these exports, or about 73.3 per cent., going to the United States. The Mexican exports were divided by grades as follows: light crude, 47.0 per cent.; heavy crude, 22.0 per cent.; tops, 3.5 per cent.; fuel oil from light crude, 24.0 per cent. The remainder, or 3½ per cent., includes the bunker fuel shipments and the coastwise trade in Mexico, which is not classified as to grades. The figures show that, in importance, the light-oil fields mean about 75 per cent. of the Mexican petroleum industry.

The production of the Panuco field has followed the general history of the American fields, and its gradual decline, which is at present foreshadowed, may be estimated as well as its ultimate economic life. On

* New York Meeting, February, 1922.

Digitized by Google

the other hand, the behavior of the light-oil fields to the south is unlike any in the world so far discovered, and as a result we have concentrated overproductions followed by sudden droughts, both sometimes equally unexpected. The coming-in of two or three gushers within adequate pipe-line facilities will flood the market with 100,000 bbl. or more a day, while the flooding by water of a particular pool will, in a few weeks, remove from the market one-half the total production of the Mexican fields.

The year 1921 saw the flooding of the southern fields, except Cerro Azul and Toteco, and the bulk of the light-oil production confined to this limited area. The present importance of these fields depends on the productivity of the Toteco-Cerro Azul area, which yields over two-thirds of the total.

The fields producing light oil, as is well known, are located along the narrow strip running from Dos Bocas, on the Tamiahua lagoon, to Alamo, on the Tuxpan river, and possibly to Furbero 30 mi. south, thus forming a slightly curved belt about 1 mi. wide and 76 mi. long called the knife-edge. Excluding the present producing areas, there are about 30 mi. that have been drained of oil and there are about 30 mi. between Alamo and Furbero, where the possibilities of extensions are questionable; 7 mi. between Alamo and Potrero, controlled by two companies, which have obtained production although its real importance remains to be proved; about 4 mi. between Potrero and Cerro Azul, likewise controlled by two companies, where the possibilities of encountering oil are not considered very promising; and an extension of 5 mi. between Tepetate and Dos Bocas, in which important development is going on at the present time and where there are strong probabilities of encountering oil although probably of a heavier grade (14° B.) than the typical product of the region.

Although it is admitted that there are possibilities of encountering oil along the entire belt between Furbero and Dos Bocas, in considering the availability of this supply for the purpose of counteracting the expected sharp decline of the present producing fields about the middle of this year, we can only consider the region between Dos Bocas and Tepetate, which so far has shown a heavier oil than to the south, and the region between Alamo and Cerro Viejo, in which producing wells have been encountered, although reports about this development have been of a contradictory nature.

In the wildcat fields, outside of the so-called knife-edge, 24 wells are being drilled at present. These wells are not near pipe-line facilities and even if some of them should prove successful their production will not compensate for the expected decline in the present fields.

Of late, considerable publicity has been given the results of drilling in the Tehuantepec region and reports of a highly productive flowing well have been circulated. However, no definite information has been obtained regarding this development other than that the well has been ruined and its production become unavailable. Although it is probable that the Tehuantepec region will again be commercially productive, the record of its wells and the small amount of prospecting being carried on tends to the conclusion that the production of this region will not increase soon enough to counteract the expected declines during the present year.

Summarizing the foregoing, we may state that there is a possibility, should an important producing field be developed between Tepetate and Dos Bocas in the next few months, that the intensive development of this area will, to some extent, make up for the decline of the Toteco-Cerro Azul pools and so maintain the Mexican production near its present high level; and that the successful intensive development of the region between Alamo and Potrero may serve the same purpose, but that in this case, owing to the large size of the holdings of two companies, the production would be more intelligently and economically handled and very likely the total exports from the Mexican fields would decline considerably below its present high rate.

## Summary

1. Production of the Panuco field will remain stationary or gradually decline during 1922. Production from the fields yielding light oil should show a sharp decline during the year, beginning some time during the summer.

2. The decline of Mexican production may be partly neutralized if the development work now being started between Tepetate and Dos Bocas proves successful; also, if the result of an intensive drilling campaign between Alamo and Potrero meets the optimistic view held by some operators.

3. Development of wildcat drilling in northeastern Mexico and the Isthmus of Tehuantepec, although of great importance as to the future supply, should not offset the sharp decline anticipated during 1922. Wildcatting is not being carried on in Mexico as intensively as the importance of the industry warrants.

4. Notwithstanding all that has been written, the conditions of the American oil industry did not warrant the sharp decline in prices during the first half of 1921 and present conditions, as regards factor of safety and stability, do not warrant any further curtailment in prices; in fact, the American oil industry, as regards supply and demand, is now under normal conditions and the oil prices should correspond to such conditions.

5. The absolute dependence of the American oil industry, in fact the world's oil industry, on Mexican production, is self-evident and a disastrous effect in the industry from a rapid curtailment of Mexican production will be the logical consequence. It follows that the intelligent development of the Mexican oil fields is a first necessity to the stability of the American oil industry.

6. Mexican taxation is now levied on a reasonable basis, which will do a great deal toward stabilizing

Digitized by Google

the world's petroleum industry, as this is absolutely dependent on Mexican and American production. The new, or export, tax levied for the sole purpose of reducing its foreign obligations, has been in effect since July 1, 1921, and must be paid by exporters of Mexican oil either in cash or in Mexican bonds.

7. Perhaps the outstanding feature of the Mexican operations during the last year has been the friendly undertone that has prevailed in all matters in which American operators and Mexican officials have come in contact, this being due primarily to the radical departure from the old practice prevailing for many years when both the Mexican Government and American operators were dealing through intermediaries, mostly attorneys, whereas all dealings during the last year have been transacted between Secretary de la Huerta of the Obregon Cabinet and the presidents of five of the leading American oil companies.

---

## Core-oven Tests*

By F. L. Wolf and A. A. Grubb, Mansfield, Ohio

The tests described in this paper were made to obtain information regarding costs, efficiency, etc. of baking cores in an oil-fired oven and two electric ovens, which were installed, early in 1920, by The Ohio Brass Co. and were used almost continuously during the rest of that year. Operating costs were rather high so a complete test was undertaken early in 1921.

The ovens are referred to in this paper as Nos. 1, 2, and 3. Nos. 1 and 2 are electric ovens of different makes while No. 3 is an oil-fired oven made by the same firm that made No. 2. The three are equipped with similar ventilating devices. They have full-height doors at front and rear. The cores are placed on iron racks, which are lifted by Cowan trucks and rolled into the ovens through the front doors. When baked, they are removed through the rear doors. Fig. 1 shows the general plan of the electric ovens while Fig. 2 shows the plan of the oil-fired oven.

The cores baked in the tests were the regular run of cores used in our foundry. They consisted largely of valve bodies up to 3 in. in size, valve fittings, and overhead-trolley fittings. They varied in weight from a fraction of an ounce to about two pounds but averaged about 3½ oz. They were composed of lake and molding sands and sand-blast dust with linseed oil and a small quantity of glutrin as binder.

Each oven was carefully studied to determine the best method of manipulation, heat absorption, heat losses, etc. Test bakes were then made and analyzed as regards heat distribution and costs.

Three special bakes were made in each electric oven in an effort to determine just what became of the power consumed. Evidently part was used in heating the iron racks, plates, etc. from room temperature to the temperature at which they left the oven, part heated the air that entered the oven when the racks were put in and taken out, part heated the air drawn through the oven by the ventilating system, and part was radiated, while the rest was probably used in actually baking the cores. For each of the test bakes, the ovens were held at 400° before putting in the racks and were brought back to 400° immediately after the racks were removed. Time was measured from the entrance of a rack until the temperature was back to 400°, after its removal, and the power consumption, heat losses, etc. over the same period were considered.

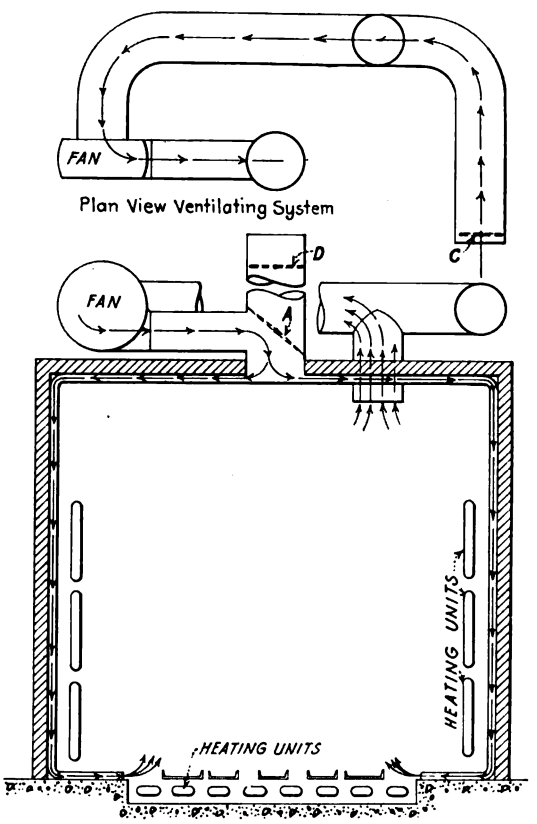


Fig. 1.—Electric core oven.

Considerable trouble was experienced in obtaining a uniform bake in the oil-fired oven-sas the heat issuing from the vents in the combustion chamber struck the cores and burnt those near the edges of the racks while others farther in were green. Bricks were removed from the upper course, at intervals of about 1 ft., and iron sheets placed so that the air from the ventilating pipes was directed down over the edge of the chamber and up through the racks and cores.

This test for uniformity of bakes was run simultaneously in the three ovens, so as to make it strictly comparable. Thirty-nine plates of test cores, five cores on each plate, were made from the same batch of core sand. Thirteen plates were placed on each of three racks together with the regular loads of cores; one was placed on each corner of the upper, middle, and lower shelves and the other in the center of the middle shelf.

*Rochester Meeting, June, 1922.

Digitized by Google

The racks were then put into the ovens and baked under the best conditions we could obtain. The cores were then broken on a Wadsworth core-testing machine and the average strength of each plate was determined.

The tests indicate that greater uniformity can be obtained in the electric ovens and the cores are probably a little stronger than in the oil-fired oven.

## Comparison of Ovens

The analyses of bakes given are not directly comparable because racks of different weights and batches of cores of different size and weights were used. The figures below show an average bake and the heat consumption based on such a bake. They are, therefore, a fair comparison of the three ovens.

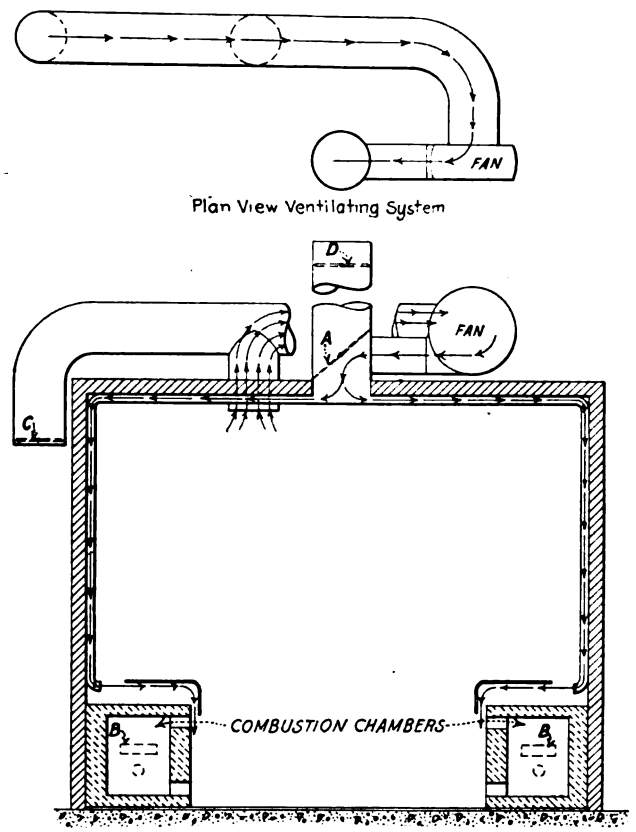

Fig. 2.—Oil-fired core oven.

| | Oven No. 1 | Oven No. 2 | Oven No. 3 |
|---|---|---|---|
| Heat used in bringing oven from room temperature to baking condition, B.t.u. | 192,700 | 191,200 | 694,000 |
| Heat radiated (or lost) while oven is closed as tightly as possible and held at baking temperature, B.t.u. per hour | 67,200 | 81,900 | 102,000 |
| Heat lost and radiated by oil-fired oven while maintaining baking temperature, burners on, fan recirculating, dampers open, B.t.u. per hour | | | 201,000 |
| Average strength of test cores baked at various points in oven, pounds | 49.8 | 48.4 | 42.7 |
| Uniformity: maximum deviation from average strength, per cent | 16.0 | 21.0 | 34.0 |
| Average bake, taken same for the three ovens: | | | |
| Weight of iron rack, pounds | 946 | | |
| Weight of plates, driers, etc., pounds | 1,111 | | |
| Weight of core, net, pounds | 282 | | |
| Average weight of cores, gross, ounces | 3.6 | | |

| | Oven No. 1 | Oven No. 2 | Oven No. 3 |
|---|---|---|---|
| Heat consumption for average bake as above, B.t.u. | | | |
| For heating rack | 36,300 | 36,300 | 36,300 |
| For heating plates, driers, etc | 42,600 | 42,600 | 42,600 |
| For heating air in oven | 5,700 | 8,500 | 80,600 |
| Radiation and other unavoidable losses | 84,500 | 108,200 | 143,200 |
| For baking cores | 33,900 | 33,000 | 47,700 |
| Total | 203,000 | 228,600 | 350,400 |
| Cost per 1000 B.t.u., cents | 0.8052 (2.75c. per kw.-hr.) | 0.8052 (2.75c. per kw.-hr.) | 0.0804 (11.14c. per gal.) |
| Cost distribution for average bake | | | |
| For heating rack | $0.290 | $0.290 | $0.029 |
| For heating plates, driers, etc | 0.343 | 0.343 | 0.034 |
| For heating air in oven | 0.046 | 0.068 | 0.065 |
| Radiation and other unavoidable losses | 0.681 | 0.872 | 0.115 |
| For baking cores | 0.273 | 0.266 | 0.038 |
| Total | $1.633 | $1.839 | $0.281 |

Core losses in ovens Nos. 1 and 3 were observed for comparison. Of 27,000 cores observed, 0.05 per cent. of those baked in the electric oven were burned and none came out green, while 1.95 per cent. of those baked in the oil-fired oven were burned and 2.14 per cent. came out green. This amounted to a loss of 30 or 40 cents on an average for each rack baked in the oil-fired oven against less than 1 cent for the electric oven.

## Conclusions

From the foregoing observations and data, we would conclude that power or fuel costs are decidedly in favor of the oil-fired oven while other considerations such as quality and uniformity of bake, core losses, convenience and cost of tending, cleanliness and noise are decidedly in favor of the electric ovens. Taking into consideration the higher losses in the oil-fired oven and the extra labor cost, the oil-fired oven cost about $0.80 per bake as compared with $1.63 for the electric oven No. 1. All of these considerations are based on the equipment and installation we now have and the present methods of manipulation, both of which we are trying to improve.

## Spies Open-stope System of Mining

Line 35, page 60, March number of Mining and Metallurgy, should read "40 per cent. higher in the shrinkage stope," instead of 4 per cent.

**Accidents** at coal mines in the United States in 1921 resulted in a smaller loss of life than in any year since 1903, according to a report compiled by the Federal Bureau of Mines. Information received from all state mine inspectors shows a total of 1973 men killed, as compared with 2271 in the preceding year, a reduction of 298 fatalities, or more than 13 per cent. The decrease was due largely to the fact that the bituminous mines were idle much of the year. The year was remarkably free from large disasters, there being but five accidents killing five or more men each, resulting in a total of 34 deaths.

# Personal Notes and Biographies

**W. J. Uren** is general manager of the Seneca Copper Corpn., Mohawk, Mich.

**Sumner S. Smith** is with the Alaskan Engineering Commission, Chickaloon, Alaska.

**R. W. Shumway** is chief engineer for the Coal River Collieries at Huntington, West Va.

**Arthur W. Duston,** who is with the Pierce Oil Corpn., has been transferred to Okmulgee, Okla.

**Louis Wade Currier** is assistant professor of mineralogy at Syracuse University, Syracuse, N. Y.

**James R. Fleming,** recently of Urbana, Ill., is mining engineer with the Mine Safety & Service Co., St. Louis, Mo.

**Frederick M. Shaw** is president of the Idaho Apache Silver Mining Co., with headquarters in the Shaw Bldg., Boise, Idaho.

**Walter Renton Ingalls** has been elected a member of the Executive Committee of the Bureau of Economic Research.

**Frank E. Nichols** recently resigned his position with the Danao Coal Mines, to become a planter at Escalante, Occ. Negros, P. I.

**Hubert Merryweather** is vice-president and general manager for the Bethlehem-Cuba Iron Mines Co., Santiago de Cuba.

**W. P. Gage,** recently with the Lone Star Gas Co., at Dallas, Texas, is now with the Humphreys Pure Oil Pipe Line Co., Houston, Texas.

**W. Armstrong Price** is engaged in subsurface geology for F. Julius Fohs, chief geologist of the Humphreys Oil Co., Dallas, Texas.

**Richard R. Smith** is on his way to South America, where he will be assistant chief engineer for the Compañia Huanchaca, Pulacayo, Bolivia.

**Rudolph C. Schappler,** recently with the Transcontinental Oil Co., Tulsa, Okla., is with the Pocahontas Copper Queen Mining Co., Mayer, Ariz.

**Ralph G. Perry,** recently with the Southern Illinois Engineering Co. at Herrin, Ill., is resident engineer with the Republic Coal Co., Roundup, Mont.

**Samuel B. Goldberg** has been promoted to the position of accountant and paymaster of the Colorado Mining Co., Aroroy, Masbate, Philippine Islands.

**W. M. Corse,** who has been with the Monel Metal Products Corpn., at Bayonne, N. J., for several years, has gone to Washington, D. C. to work with the National Research Council.

**James W. Wilson,** superintendent Lower Departments of the National Tube Co., has been made assistant to the vice-president of that company and has moved from McKeesport, Pa., to Pittsburgh.

**Arthur S. Dwight,** Lieutenant-Colonel in the Engineer Officers Reserve Corps, has been placed in the general assignment group and has been reserved for duty under the direction of the Assistant Secretary of War, General Staff, in time of emergency.

**Percy E. Barbour,** Major, Engineer Officers Reserve Corps, has been attached to the 342nd Engineers, 12th Corps, in the Second Corps Area. This regiment is assigned to Army Corps engineer service.

**L. J. Buck** has severed his connection with the National Carbon Co., and has become sales representative in the United States for the British America Nickel Corpn., Ltd., with offices in the Canadian Pacific Bldg., New York City.

---

## Verplanck Colvin

VERPLANCK COLVIN, a member of the Institute for 39 years, died on May 28, 1920, but notice of his death did not reach the secretary's office until early this year.

Mr. Colvin was superintendent of the New York State Land Survey, and had a long record of service to his native state. He was born in Albany, N. Y. on Jan. 4, 1847, and was educated at the Albany Academy and by private tutors.

At Nassau, Rensselaer County, where the family lived during his boyhood, he indulged his taste for outdoor life and laid the foundation of his love for topographical science by preparing topographical maps of the country. He studied law under his father and practiced successfully in the minor courts, but inclined more and more to scientific pursuits. He joined the Albany Institute and organized a successful course of free scientific lectures in the State Geological Hall.

In 1865 he began his exploration of the Adirondack wilderness, at his own expense, and corrected many errors in existing maps of that region. In 1870, he

Digitized by Google

made the first ascent and measurement of the height of Mt. Seward, and about that time discovered the remarkable errors of the compass needle in northern New York, which render bearings taken in many parts of those mountains almost valueless. In 1869, he made a careful geologic and topographical survey of the Helderberg Mountains, a brief account of which was published in *Harper's Magazine*. During the latter part of the winter of 1870 he traveled extensively through the southern states, and in 1871 he crossed the great plains to Colorado, visiting Wyoming, Nebraska and the Black Hills. He was the first to ascend, describe and map the highest peaks in the Rocky Mountains, and later wrote an article for *Harper's Magazine*, entitled, "The Dome of the Continent," which caused the name "Dome State" to be first applied to Colorado. He was elected an honorary member of the Rocky Mountain Club of Denver, an honor rarely conferred.

In 1872, Mr. Colvin induced the New York State Legislature to make an appropriation for the state survey in the Adirondack region, and in the same year he was made superintendent of that work and of other state surveys. He traced the Hudson River to its highest pond source, Lake Tear of the Clouds, on the south flank of Mt. Marcy. In 1873 he was appointed one of the Commissioners of State Parks of New York. In 1875, he made the first true measurement with level and rod of Mt. Marcy, the highest peak in New York State.

His services have been of great value to the state and to science at large, and the highest mountain on the east shore of the lower Ausable Lake, in the eastern Adirondacks, bears his name.

In 1888, when the national government was proposing to erect new gun foundries, he showed in an able paper that the most secure location for the factory was at the Watervliet Arsenal, near Albany. Congress adopted his views and he was called into consultation by the ordnance officers of the United States Army.

Mr. Colvin also acted as consulting engineer on location of railroads. He was at one time president of the Schenectady and Albany Railroad Co. and was a director and officer in other railroad companies, among them, the Canadian Pacific Railway.

## Donald G. Campbell

DONALD G. CAMPBELL was drowned at Hoggum Bay, near Olympia, Wash., on Dec. 18, 1921, while on a duck-hunting expedition. He was a member of the firm of Campbell, Wells & Elmendorf, of Seattle, and had been a member of the A. I. M. E. for five years.

Mr. Campbell was born at Port Arthur, Ont., in 1887. He took the B. S. degree at Whitman College in 1912; the M. A. degree at Columbia University in 1913 and E. M. in 1914. In 1914–15, he was instructor of metallurgy in the University of Washington. In 1915–16, he did exploration and development work at mines in southern Idaho, and was later connected with the A. S. and R. smelter at Tacoma, Wash. In 1916, he established the firm of Campbell, Wells & Elmendorf. During the first year of the firm, he discovered palladium in lode deposits near Ketchikan, Alaska. In 1918, he acted as consulting engineer for various mining properties being developed in the Northwest. During 1919–20 he acted as engineer and metallurgist for a company developing a lode tin property near Nome, Alaska, taking his family with him, and living for over a year at the camp. In the past year he has been engaged in work for the Wrangell Pulp and Paper Co., looking toward the development of this new industry in Alaska.

He wrote, "The Flotation Process," published by the McGraw Hill Co., and "Palladium in Alaska Lode Deposits," which appeared in the *Mining & Scientific Press* of October, 1919.

Mrs. Campbell and two sons, Donald Durant and Gordon Freeston, six and four years old, survive him.

## Leonard H. Whitney

LEONARD HILLARD WHITNEY was killed in the Katherine mine, near Kingman, Ariz., on Dec. 17, 1921. While engaged in erecting a hoisting engine, Mr. Whitney was struck in the head either by the fly wheel, or by a piece of metal thrown from it, and was killed instantly. He had been assistant superintendent of the Katherine mine for some time, and was spoken of as an unusually promising young engineer and a man of most excellent personality.

Mr. Whitney graduated from the University of Illinois in June, 1917, but had interrupted his college course to take part in the great war. He obtained a commission as First Lieutenant at the Officers Training Camp at Fort Sheridan, and served overseas.

He was 27 years old, and had been a member of the A. I. M. E. for four years.

## Necrology

THE deaths of the following members were reported to the Secretary's office during the month Feb. 18, to Mar. 20, 1922.

| Date of Election | Name | Date of Death |
|---|---|---|
| 1921 | Baldwin, George P. | Jan. 28, 1922 |
| 1897 | Burger, C. C. | March 10, 1922 |
| 1915 | Caples, James Watts | Sept., 1919 |
| 1892 | Clement, F. H. | Feb. 18, 1922 |
| 1915 | Hoffman, Lloyd | Feb. 21, 1920 |
| 1892 | Huntley, Dwight B. | March, 1921 |
| 1919 | Lindstrom, Reuben L. | Dec 12, 1921 |
| 1914 | Magnus, Benjamin | March 12, 1922 |
| 1917 | Salmon, George J. | March 1, 1922 |
| 1905 | Steel, Henry | |
| 1919 | Thornton, Edmund A. | Jan. 9, 1922 |
| 1918 | White, John H. | Dec. 28, 1921 |

# Institute Affairs

## Transactions Desired

IT HAS been suggested that when members of the Institute, by reason of their change of profession and interest, resign from the Institute, their collection of the TRANSACTIONS may be of no further use or interest to them and that these might well be donated or sold to the Institute as the occasion requires.

The Institute has a considerable stock of back TRANSACTIONS with the exception of a few numbers which are out of print. These scarce volumes are always in demand and it would not only benefit the Institute but satisfy a large number of requests if we could obtain these volumes. It is probable that the estates of our deceased members may be unaware of any recipient who would appreciate a collection of the TRANSACTIONS, and we wish that our members would have this in mind and make suggestions in cases that come to their notice.

PERCY E. BARBOUR.

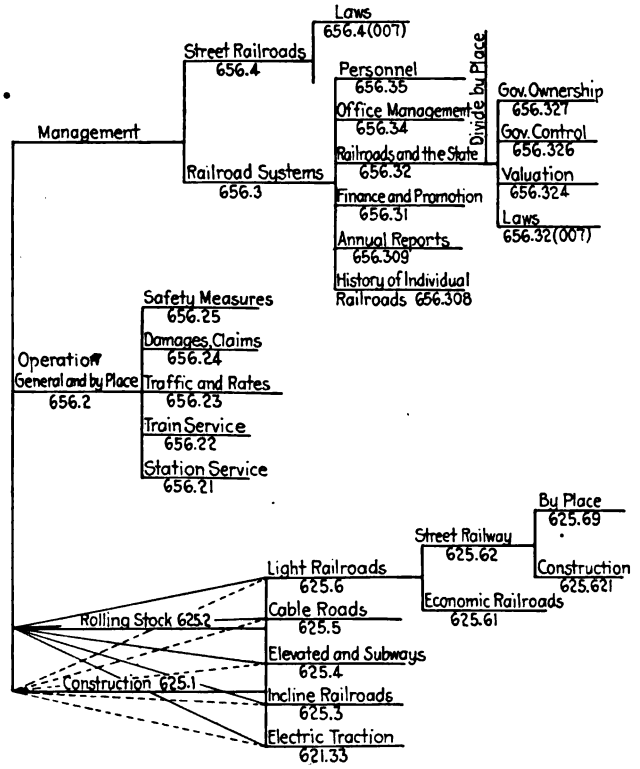
## Cataloging and Recataloging the Engineering Societies Library

CATALOGS, bibliographies and indexes are the tools with which the student quarries from a library the information that will help him in his researches. Realizing fully the need for a full catalog of this library, the Library Board has made the preparation of one fitted to act as a foundation for future work its chief task for the past two years. The variations in the catalogs of the four libraries that make up the Engineering Societies Library are being removed by the systematic recataloging now in progress, and at the same time the large accumulation of uncatalogued material is being made accessible.

All periodicals, including the transactions of societies, except a few of minor importance, are now fully catalogued. All books acquired during the past four years, and all older editions of these titles, have been handled.

As the new catalog begins to function, there is no doubt of its value or of its need. With less than three-quarters of the books completely analyzed, the efficiency of the library has increased in amazing proportions.

The Brussels classification is used. For example, in the subject of Railroads, it is not enough to know that there are books on locomotives, terminal stations, signals, road beds, rolling stock, etc.; the classifier must first realize that the two main divisions of this subject are the Engineering or Construction side, and the Transportation or Economic side, and that the literature on the subject will naturally fall in one of these groups. By the charting of subjects, the possibilities of the field are apparent. The accompanying chart is given as an example of the layout of a subject. It shows only the main groups. More specific divisions are used in practice.



RAILROAD CLASSIFICATION CHART.

The next step is to get at the correct subject of each book. This is frequently an easy task; the author has a definite purpose, he states his case and gives a comprehensive outline of his theme. Such books, including textbooks, histories and simple treatises, are not difficult to handle, but many books are so involved that much time and study must be devoted to them before subjects can be correctly determined. The classifier can never stop at the title page. Titles are misleading, and even an author's preface often gives an incorrect statement of what the book proposes to treat. Therefore the text of all books must be thor-

Digitized by Google

oughly perused, and each one considered on its own merit, as well as in relation to like kinds, so that all treating of one subject may fall into the same group. Very often one title will contain splendid material on five, ten or twenty subjects.

Again, books are found to contain subjects quite foreign to each other. A work on the application of electricity to some special industry makes a contribution to both electricity and the industry, and may also contain a few excellent chapters on foreign trade.

Every book must be given a symbol by which it can be identified. If there are 150,000 books there must be as many symbols. A record of these symbols must be made, together with the author and title which they represent. This also serves as an inventory of the books as they stand on the shelves.

Every book has to be handled from 15 to 20 times after its receipt from the publisher before it is ready for the shelves. Most of these are mechanical processes, but at least two of them, the classifying and cataloging, are quite the reverse.

Lack of money has prevented the addition of some equipment which would speed up the work and also afford better facilities for using the catalog. A specially designed table is needed, to be placed in the reading room near the catalog, on which the more important published indexes could be placed and where readers could consult the catalog trays. This would bring card and book bibliographies together and facilitate consultation of the catalog.

Inadequate funds have also made it necessary to shelve hundreds of volumes of periodicals without binding, tied in volumes. This is a temporary measure, and when these volumes are to be bound they will have to be collected again. Until bound, the chances of loss and mutilation, of course, are great. Stress is laid upon this condition because the mechanical handling by the catalogers of long sets of magazines, often made up of 50, 75 or 100 volumes, has in great measure hindered the work.

It may be safe to say that the end is in sight, but it is impossible to tell how many months may elapse before the work is completed.

HARRISON W. CRAVER.

## Directors Meeting

AT THE executive session of the meeting of the Board of Directors held on Feb. 21, 1922, the following were present: Arthur S. Dwight, president; W. H. Aldridge, George D. Barron, William H. Bassett, Galen H. Clevenger, W. M. Corse, A. R. Ledoux, Edwin Ludlow, R. V. Norris, Charles F. Rand, J. V. W. Reynders, George Otis Smith and W. E. Wrather.

The following officers were elected: J. V. W. Reynders, first vice-president; Charles F. Rand, treasurer; Frederick F. Sharpless, secretary; Percy E. Barbour, assistant secretary.

Committees were elected as follows:

*Executive Committee.*—A. R. Ledoux, chairman; Arthur S. Dwight, Edwin Ludlow, Charles F. Rand and J. V. W. Reynders.

*Finance Committee.*—Walter H. Aldridge, chairman; George D. Barron and Galen H. Clevenger.

*Papers and Publications Committee.*—Sydney H. Ball, chairman; F. F. Sharpless, secretary; Percy E. Barbour, Galen H. Clevenger, B. B. Gottsberger, Henry D. Hibbard, Robert Linton, Paul D. Merica, R. V. Norris, George C. Stone, Chester W. Washburne, Arthur L. Walker.

President Dwight appointed the following Committee on Membership: E. De Golyer, chairman; William Young Westervelt, vice-chairman; William M. Corse, H. G. Moulton and C. Minot Weld.

After the executive session, an open session was held and, in addition to those mentioned above, there were present:

F. F. Sharpless, secretary; Percy E. Barbour, assistant secretary; L. K. Armstrong, H. B. Fernald, F. L. Garrison, W. Spencer Hutchinson, Oscar Lachmund, Robert Linton, Horace F. Lunt, W. E. McCourt, P. N. Moore, R. A. Parker, Maj. C. R. Pettis, U. S. A., F. W. Sperr, Arthur Thacher and W. Y. Westervelt.

The Board of Directors, desiring to record its appreciation of the arduous work of the various committees charged with the conduct of the 1922 annual meeting of the Institute in New York, unanimously adopted the resolution that was printed on page 16 of the March MINING AND METALLURGY.

The following dates, for meetings of the Board of Directors for the next eleven months were agreed upon: March 24, April 28, May 19, June 23, Sept. 22, Oct. 20, Nov. 17, Dec. 15, 1922 and Jan. 26, 1923.

A budget for the year 1922 was presented by the Finance Committee and adopted. The report of the Treasurer and Finance Committee was presented in writing, was accepted, and ordered filed.

President Arthur S. Dwight announced the appointment of John H. Janeway as member of Library Committee.

Actions of the Executive Committee were approved as follows: Authorization of Local Section at Kingman, Ariz.; election of 14 Members, 13 Associates and 26 Junior Associates; approval of change of Constitution of American Engineering Standards Committee.

The report of representatives on American Engineering Council for the year 1921 was approved.

Action on the report of the Joint Committee on Code of Ethics for Engineers was deferred until the next meeting.

Twenty-three Members, 9 Associates and 35 Junior Associates were elected to membership; two changes of status from Associate to Member, one from Junior Associate to Associate, and two from Junior Associate to Member; eight were reinstated to membership; the dues of one number were remitted for the years 1918 and 1919; 94 resignations were accepted.

Digitized by Google

The Mining and Metallurgical Society of the University of Alabama was admitted as an Affiliated Student Society.

President Dwight was authorized to appoint a committee to coöperate with the War Department in the matter of Industrial Preparedness.

An invitation to the officers and directors to attend the annual meeting of the Canadian Institute of Mining and Metallurgy was referred to President Dwight with power. A committee composed of Bradley Stoughton, chairman, J. V. N. Dorr and R. B. T. Kiliani was appointed to attend this meeting.

## Significance of Standardization in America*

THE significance and importance of standardization to industry and to the Federal Government seem almost axiomatic to those of us who have been actively interested in standardization work for a number of years, and since the present is a particularly opportune time for the launching of extensive coöperation between government and industry, it seems well to point out the opportunities and means of such coöperation in industrial standardization.

Of the many advantages to be derived by both industry and the Government from standardization along national lines, the most important seem to be:

1. Mass production, with its obvious advantage to the producer, means reduction in cost. Competition engendered by such production insures to the consumer, including the Government, the benefit of reduction in price.

2. Elimination of wide varieties and sizes permits producers to concentrate on those retained, and facilitates improvements in method and equipment that will ultimately result in the elimination of waste and reduction of cost to the consumer, including the Government.

3. Putting all tenders on an easily comparable basis promotes fairness in competition in both domestic foreign trade, to the benefit of both producer and consumer.

4. Elimination of indecision in both production and utilization removes a prolific cause of inefficiency and waste.

5. Stabilization of production and employment means for the producer uninterrupted manufacture from stock during periods of depression. This is of vital interest to the Government as being of benefit to the country as a whole.

6. Accumulation of stock means prompt deliveries by the producer, and eliminates the necessity of the Government itself carrying a large inventory of material.

* Excerpts from paper presented before the Washington, D. C. Section of The American Society of Mechanical Engineers, Dec. 9, 1921, by A. A. Stevenson, chairman, 1921, American Engineering Standards Committee.

In both Great Britain and Germany, national standardization is being carried on intensively. For reasons for which neither can be blamed exclusively, there is no doubt that the industries of this country and the Government Departments in many instances have not coöperated in a way to insure best results in standardization along national lines. A recent event of unusual importance was the organization of the Federal Specifications Board, for unifying the specifications for all Government purchases, military as well as non-military.

In order that standardization along national lines may be brought about, it is necessary that there be some central body to act as a clearing house in standardization work. It is essential that there be brought together information concerning the organizations by which standards have been formulated and are being promulgated and details relating to such standards as are already in use. From the central body charged with the duty of collecting this information, it should be transmitted promptly wherever needed to insure the elimination of conflicts in the formulation of standards. Success to be expected from a central body organized for the purposes just stated obviously depends upon the authority invested in it, and the recognition received by it from the organizations throughout the country doing standardization work.

As a result of the work in which the American Engineering Standards Committee is now actively engaged, existing conflicting standards are being brought into harmony, and there are being created truly representative committees to formulate new standards. The methods employed obviously differ somewhat from methods utilized hitherto, and it must be acknowledged that they are not yet fully understood by many of the organizations in America that should be coöperating in standardization along national lines.

The real significance of standardization to industry and the Federal Government—what it may mean and what it can accomplish, will not be fully realized until there is sincere coöperation which is sympathetic, systematic and comprehensive, between industry and the Federal Government, in which coöperation the general consumer has a part.

## Last Words of Foolish Miners

THESE typical sayings are from the Miners' Safety and Health Almanac, issued by U. S. Bureau of Mines, Washington, D. C.

"I wonder if this is a live wire. I'll touch it and see."

"Cap crimpers are toys for kids; see me use my teeth."

"There comes the trip. Wonder if I can get across the track ahead of it."

"This must be a missed shot. I'll dig in and find out."

"I don't need a safety line; this is easy."

"This roof looks bad but I'll risk it."

# Official Institute Reports for the Year 1921

## Abstract of Report of President

THE business depression has borne severely upon our members, and the shutting down of mines and metallurgical works has thrown so many of our younger members out of employment that we have not only had a great many resignations but also there are nearly 500 who, under the Constitution, should be dropped for non-payment of dues for two years; and further, nearly 1000 who have found it impossible to meet the call for dues during the past year. This has caused a severe drop in our revenue, which was partly covered by the 1200 new members who joined the Institute during the year, and by the generous reply to the appeal for a voluntary contribution made at the beginning of the year that brought nearly $18,000 into the treasury.

In spite of this, we are able to show for 1921 an excess of receipts over expenditures of $41,103.52, from which we have deducted the deficit on the books of the Institute of $3,178.74, closing the year with a net excess of $37,924.78, an amount sufficient to pay for the publication of all papers on hand and leave a cash surplus of over $7000.

Probably the greatest item of saving that was accomplished during the past year was in the cost of the magazine. A few comparative figures on this subject may be enlightening to some of our members. During the year 1919, we published the old bulletin at a cost of $55,000, with a revenue from advertising and sales of $18,000, making a net cost of $37,000. In 1920, MINING AND METALLURGY was started, and the cost for the first year was $41,000 with a revenue of $27,000, leaving a loss for the year of about $14,000. In 1921, the cost of MINING AND METALLURGY was $35,000, with a revenue of over $30,000, making a net loss for the year of only $4500, and the increasing amount of advertising makes it entirely probable that in the year 1922 the magazine will become entirely self-supporting. During my visits to the local sections on the Pacific Coast and in the interior, I found that the members of our Institute residing in the mining camps of the West look upon the magazine as the main tie with the Institute.

We have also economized in expenditures for our Increase of Membership Committee. In spite of the serious depression in all lines of mining business, our membership has had an increase of 1235 names during the past year, and, with the exception of the year 1920, it shows the greatest increase of membership of any year in the history of the Institute.

Three new local sections were organized during the year: Oregon, Philadelphia, and West Virginia and Eastern Kentucky at Charleston, West Va. Two other sections, at Tampico, Mexico, and Kingman, Arizona, have made application and been granted their request for authority to form sections and are now completing their organizations.

Another most interesting feature of the past year was the presentation of the John Fritz Medal to Sir Robert Hadfield in England and M. Charles Eugène Schneider in France by the John Fritz Medal Board, supported by a delegation of engineers from the four Founder Societies.

The power of the combined engineering talent of the country is needed to solve our present problems. The first essential is the completion by American engineers of the organization of the Federated American Engineering Societies, and the spread of that organization throughout the country. To accomplish this, our local sections should coöperate with the local sections of the other Founder Societies and should organize local engineering societies that can be formed into active members of the Federated Societies.

EDWIN LUDLOW.

---

## Abstract of Report of Secretary

THROUGH the efforts and generous assistance of our members, MINING AND METALLURGY, during recent months, has shown constant improvement. For the year 1921, the net cost of the magazine was about fifty cents per member, per annum. Occasional letters are received criticizing the Board for producing this publication, but they are more than offset by letters of approval. When the full purpose of the publication is appreciated, criticism ceases.

The elimination of MINING AND METALLURGY and reversion to free distribution of all papers to all members, whether desired or not, would mean such a heavy additional expense that the number of papers would have to be much curtailed.

The generous coöperation of members in sending for only such papers as they particularly desired has saved the Institute thousands of dollars. A plan is being worked out that will materially assist in securing a prompt distribution to members of all pamphlets dealing with subjects in which they are especially interested.

Digitized by Google

Thanks to the watchful care of the president, the Finance Committee, the support given to both by the Board, and to a generous voluntary contribution from many members, the deficit of a year ago has been wiped out and 1921 ends with a creditable balance on hand. Much of this apparent surplus, however, is earmarked for the payment of 1921 obligations. There is an accumulation of unpublished pamphlets, which it is hoped to get into the form of TRANSACTIONS early in 1922; the balance carried forward will probably enable this to be done.

The income for 1922 is uncertain in amount. Many of our members are out of employment and the earnings of still more are so small as to make even our small dues a burden. In view of the present depressed condition in the mining and allied industries, the Finance Committee has suggested a budget as small as possible consistent with the efficient operation of the Institute.

One of the most successful meetings ever held by the Institute was that of its 50th Anniversary, which was held at Wilkes-Barre, in September. The credit for the success of this meeting rests upon the members of the anthracite region and their able local chairman, R. V. Norris.

The following names have been added to the Honorary Membership roll during the year: William Cuthbert Blackett, Marshal Ferdinand Foch, Frank William Harbord, H. O. Hofman, C. McDermid.

We record with sorrow the passing of many prominent members of whom the following deserve special mention: B. B. Lawrence, who had served the Institute as manager, councillor, and vice-president; J. W. Richards, vice-president twice, councillor, and director; Stuart M. Buck, manager; and our honorary member, Prof. D. C. Tschernoff.

Since the report of the secretary for the year 1920, the Committee on Mining Methods has become very active, under the chairmanship of John E. Hodge.

In former days, much less thought was given to the younger members of the profession than is the case today. It is now realized that the students of today are the members of tomorrow and that the interest of the older members of the profession should be directed toward the younger members almost as soon as they start in our direction.

The record of the Employment Bureau, supervised by the four Founder Societies, for the year is enviable.

During 1921, 1905 applications for positions were received and it is known that 1365 men were placed, and probably many more who failed to notify the able manager, W. V. Brown, of their having obtained employment through the Bureau.

There is only one reason why more men have not been placed; lack of funds with which to work. It has cost the interested societies about $16,245 to place these men, and this sum is as large as the societies have felt that they could afford to devote to the work. A paid bureau has been considered, but so far no practical method of operating it has been found.

Those men who have secured employment could well afford to contribute for the benefit of those who have not, and yet there are certain disadvantages connected with a paid service; its apparent commercial aspect makes the plan questionable. The problem is not easy, and it is one of the most important confronting the members of the Institute who happily are not upon the list of the unemployed.

F. F. SHARPLESS.

## Report of Membership Committee

The number of applications for membership received in 1921 was 898. The number of persons elected was 1324, of whom 1284 accepted and became members. The total membership Dec. 31, 1921, was 10,205, as against 9323 on Dec. 31, 1920. The changes in membership during the year were as follows:

| | | |
|---|---|---|
| Total membership, Dec. 31, 1920 | | 9,323 |
| Elected and placed on rolls in 1921 | 1,251 | |
| Reinstated | 33 | 1,284 |
| | | 10,607 |
| Loss by resignation in 1921 | 196 | |
| Loss by death in 1921 | 88 | |
| Loss by suspension in 1921 | 118 | 402 |
| | | 10,205 |

This membership is distributed as follows:

| | |
|---|---|
| Honorary members | 19 |
| Members | 7,909 |
| Associates | 951 |
| Junior Associates | 1,326 |
| Total membership, Dec. 31, 1921 | 10,205 |

## Report of Library Committee

The library was used during the year by approximately 35,000 persons. Of these 26,840 visited it, the others referring to it by mail or telephone. The number of visitors was 12 per cent. greater than in 1920.

The accessions to the permanent collection were 4210 pieces; of these 414 were purchased, 3129 were gifts. The library contained, on Dec. 31, 1921:

| | |
|---|---|
| Volumes | 118,980 |
| Pamphlets | 34,091 |
| Maps and plans | 555 |
| Searches | 3,904 |
| Total | 157,530 |

Recataloging has been carried on as actively as funds permitted. Searches, translations, and photoprints have been made for 2342 persons. The library has continued to compile copy for the Mining and Metallurgical Index. Arrangements have been made to lend duplicate books to members of the Institute.

Digitized by Google

## Financial Statement

As examined and approved by the Finance Committee and Board of Directors at their meeting on Jan. 27, 1922.

### Balance Sheet, as of Dec. 31, 1921, American Institute of Mining and Metallurgical Engineers, Inc.

ASSETS

| | | |
|---|---|---|
| Equity in U. E. S. land and building | | $486,792.79 |
| Books in the library | | 40,000.00 |
| Investments | | |
| James Douglas Fund | $ 99,999.36 | |
| R. W. Hunt Fund | 7,497.33 | |
| Life Membership Fund | 9,415.63 | 116,912.32 |
| Cash | | |
| should be invested | $ 2,950.33 | |
| in banks, general funds | 31,873.80 | |
| petty cash, in office | 1,050.00 | 35,874.13 |
| Suspense accounts | | 625.30 |
| Paper on hand | | 8,771.93 |
| Insignia on hand | | 185.34 |
| | | $689,161.81 |

LIABILITIES

| | | |
|---|---|---|
| Accounts payable | $ 4,180.13 | |
| | 391.46 | $ 4,571.59 |
| Due the James Douglas Fund | $100,000.00 | |
| Due the R. W. Hunt Fund | 7,500.00 | |
| Due the Hadfield Fund | 1,154.51 | |
| Due the Thayer Fund | 8.14 | |
| Due the Life Membership Fund | 11,200.00 | |
| Total of above | | 119,862.65 |
| Reserve for Life Memberships | | 40,000.00 |
| Surplus as follows: | | |
| Contributions by Carnegie and others to real estate | $486,792.79 | |
| Excess of cash receipts over payments Dec. 31, 1921 | 37,934.78 | 524,727.57 |
| | | $689,161.81 |

### Receipts and Expenditures for the Twelve Months Ending Dec. 31, 1921

RECEIPTS

| | |
|---|---|
| Dues, Arrears | $ 3,483.58 |
| Current | 98,505.81 |
| New members | 12,822.42 |
| In advance | 2,115.43 |
| Initiation fees | 10,583.00 |
| Voluntary subscriptions | 17,811.65 |
| Sale, Transactions | 4,057.57 |
| Binding | 8,976.69 |
| Magazine | 4,140.38 |
| Pamphlets | 562.15 |
| Indexes and Emmons | 267.05 |
| Pyrometry volume | 764.07 |
| Raymond volume | 33.00 |
| Year Book | 111.80 |
| Pins and fobs | 387.85 |
| Miscellaneous receipts | 174.03 |
| Advertising | 26,370.32 |
| Interest on bank balances | 1,070.25 |
| Life memberships | 442.17 |
| Douglas fund | 6,167.34 |
| | $198,846.56 |

EXPENDITURES

| | |
|---|---|
| Year Book | $ 4,043.41 |
| Magazine | 35,055.28 |
| Technical papers | 6,920.51 |
| Authors reprints | 198.40 |
| Transactions, Vols. 1 to 63 | 2,350.67 |
| Vols. 63 | 1,600.00 |
| Vols. 64 | 10,849.31 |
| Vols. 65 | 4,158.27 |
| Vols. 66 | 1,269.52 |
| Index and Emmons volume | 66.43 |
| Pyrometry volume | 486.77 |
| Raymond volume | 21.95 |
| Meetings | 2,891.09 |
| Local Sections | 2,645.25 |
| Technical Committees | 273.25 |
| Office space | 3,274.00 |
| Library | 9,249.96 |
| Federated Am. Eng. Societies | 12,660.22 |
| Amer. Engr. Standards Committee | 1,500.00 |
| Salaries not otherwise distributed | 34,428.89 |
| Accounting Department | 7,954.83 |
| Membership Department | 3,795.28 |
| Stationery and supplies | 2,922.12 |
| Telephone and telegraph | 1,525.34 |
| Postage for general office mail | 2,054.20 |
| Furniture and fixtures | 1,674.69 |
| Miscellaneous office expenses | 581.48 |
| Secretary's traveling | 959.85 |
| President's traveling | 720.38 |
| Legal expenses | 325.00 |
| Miscellaneous Institute expenses | 1,057.73 |
| Pins and fobs purchased | 228.98 |
| | $157,743.04 |

## Report of the Committee on Papers and Publications

During the year 1921, 138 papers were submitted to the committee. Of this number 71 were accepted for presentation at a meeting of the Institute, 42 were declined, 13 were accepted for publication only in MINING AND METALLURGY, and 12 were returned to the authors by request or for revision. The principal papers have been printed in full and abstracts of all the papers were printed in MINING AND METALLURGY.

The papers presented at the New York meeting may be classified as follows: iron and steel, 9; mining and milling, 4; non-ferrous metallurgy, 5; Institute of Metals Division, 2; coal, 7; petroleum and gas, 6; industrial relations, 2; geology, 2.

For the meeting, in Wilkes-Barre, 45 papers were submitted, of which 24 were accepted and printed. In addition, 9 papers were presented at the Americanization session and four papers published by the Society of Economic Geologists were presented at the joint sessions with that society. Most of the papers presented at this meeting dealt with coal.

During the year, there have also been printed Volumes LXIV and LXV, and Volume LXVI is ready to be sent to the printer.

# Local Sections and Affiliations

## Pennsylvania Anthracite Section is Active

THE Pennsylvania Anthracite Section had a very enthusiastic meeting on Feb. 4. D. C. Ashmead's paper, "Can Anthracite Mines be Operated Profitably on More than One Shift?" was presented and was discussed by the 52 members who were present.

George Stevenson, of Scranton, spoke on licensing of engineers, and William Griffith gave a talk on the consumption per capita of anthracite coal in large cities and rural districts. He showed that as the differential in price between anthracite and bituminous increases, the consumption per capita decreases.

## Institute of Metals Division

AT THE annual business meeting of the Institute of Metals Division, held on Feb. 21, 1922, the secretary, W. M. Corse, made a short informal report, saying that the membership of the Division runs well toward the thousand mark at the present time, and that the next meeting, to be held in conjunction with the American Foundrymen's Association, will be held in Rochester during the week of June 5, instead of in Cleveland in April.

The election of officers, which takes place every second year, resulted as follows: chairman, William B. Price; vice-chairman, George K. Elliott; secretary and treasurer, William M. Corse; members of executive committee, George K. Elliott, William Campbell, H. M. Lane, J. A. Capp, C. T. Bragg, E. E. Thum, Lawrence Addicks, W. A. Cowan, George F. Comstock, H. M. Williams.

## Copper as Well as Oil Discussed by Mid-Continent Section

THE regular monthly meeting of the Mid-Continent Section (formerly the Tulsa Section) was held on Feb. 24, with a good attendance. Two very interesting papers were given.

V. H. Hughes, petroleum geologist, gave a brief talk on The Conservation of Oil and Gas, in which he described the enormous waste of gas in the Oklahoma fields in the past and, also, some of the waste that is going on at the present time. He said that when the Cushing development was at its height over 500 million cubic feet of gas went to waste every day, and that this gas had a high gasoline content. He called attention to several of the fields in Oklahoma that are being drilled into water, and discussed methods by which this could be prevented.

Herbert G. Officer, who has spent about six years in Chile as head of the exploration work for the Anaconda Copper Mining Co., gave a paper on The Copper Mining Industry of Chile, illustrated by charts and maps. The following properties were discussed in detail: Chuquicamata, Potrerillos, Santiago Mining Co., and Braden mines. The magnitude of the industry in Chile was especially stressed. Mr. Officer said: "The total ore reserves are over 1200 million tons of 2 per cent. copper content. With an 80 per cent. metallurgical recovery, this would give 38,400 million pounds of copper available for market. The ore reserves of the seven American porphyry coppers (Utah, Nevada, Chino, Ray, Miami, Inspiration and New Cornelia) are about 800 million tons of 1.5 per cent. copper ore. With a recovery of 25 lb. per ton, there would be 20,000 million pounds of copper available for market. In other words, the American owned mines of Chile have 1.9 times as much tonnage and twice as much recoverable copper as the seven great "porphyry" mines in the United States. Of course we have other large resources, such as Lake Superior, Butte, Bisbee, and other mines, but these figures point to the day when Chile will once again lead the world in the production of copper. The present productive capacity of the United States is about two billion pounds per year. When the present plans are completed, Chile will be producing about one billion pounds of copper per year."

Two weeks before, on Feb. 11, the Mid-Continent Section took part in the entertainment of Dean Cooley, president of the Federated American Engineering Societies. The officers of all the local sections of the engineering societies represented in the F. A. E. S. gave a breakfast for Dean Cooley in the Hotel Tulsa; there was a luncheon at the City Club, and a banquet in the evening at the Hotel Tulsa. About 130 members attended the banquet. Alf. G. Heggem was toastmaster and M. M. Valerius had charge of all arrangements. Dean Cooley's visit was thoroughly enjoyed by all who had the pleasure of meeting him.

The meetings of the section are held regularly, the

Digitized by Google

last Friday of each month, in the Y. M. C. A. at Tulsa, and plans are being laid to have some very interesting programs presented at the next four meetings. An outline of the program for these meetings will be printed in MINING AND METALLURGY.

## Mining Law Revision

THE subject before the San Francisco Section at its meeting on Feb. 14 was The Proposed Changes in the Mining Law of the United States. William E. Colby was the speaker of the evening. He treated the subject under three heads: the good points, the doubtful points, and the bad points of the new law. After the formal address, Mr. Colby answered questions and there was general discussion.

## Affiliated Student Societies

**University of Minnesota.**—The School of Mines Society is especially interested in the new building that is being erected on the campus. This building will

ARCHITECT'S PHOTOGRAPH OF THE MINES EXPERIMENT STATION BUILDING BEING ERECTED ON THE CAMPUS OF THE UNIVERSITY OF MINNESOTA.

house the Mines Experiment Station of the University of Minnesota and the North Central Experiment Station of the U. S. Bureau of Mines. It is expected to be the best laboratory in the world for the study of iron and manganese ores.

At the first meeting of the society in January, Roger W. Gannett, '18, spoke on Geological Exploration in Indo-China. Mr. Gannett recently returned from Yunnan Province, in southern China, where he spent considerable time making a survey of the mineral resources of the region. He explained in detail the methods used in reopening for examination the old Chinese workings on the lead-silver deposits, and discussed the geology of the ore-bearing formations.

The following meeting was addressed by Lyndon L. Foley, '18, who has been engaged for several years in an examination of oil possibilities on the island of Trinidad. Mr. Foley illustrated his lecture with slides, and outlined some of the obstacles under which exploration work is carried on in a tropical country.

On Feb. 11, E. J. Schrader, '05, spoke of the problems of reopening abandoned mines for examination and possible operation. At the following meeting, Mr. Schrader spoke on General Cyanidation Practice, outlining the ideal conditions under which the cyanide method would be most efficient, and explaining the ways in which actual conditions could vary from the ideal without encountering prohibitive losses and increased costs.

**University of Alabama.**—The students in mining and metallurgy have organized a society called the Mining and Metallurgical Society, which has a membership of 25 and includes not only students of mining and metallurgy but other students who are interested. The officers are: T. W. Newton, president; J. B. Martin, secretary.

The object of the association is to promote fellowship among the members and the discussion of current mining and metallurgical topics and literature. Meetings are held twice a month, at which papers are presented by prominent mining men and members of the faculty and also some of the student members.

**Montana State School of Mines.**—The Mining Society elected officers on Feb. 16, 1922. Ellis P. Frink is president; Wallace Lee, vice-president; William A. Scarlett, marshall; Alex. M. McDonald, secretary.

The society voted to change its name to The Anderson-Carlyle Technical Society, in honor of two men from the school who lost their lives in the World War.

## Annual Meeting of the Woman's Auxiliary

THE sixth annual meeting of the Woman's Auxiliary to the A. I. M. E. was held in New York, on Feb. 22, with Mrs. Arthur S. Dwight, the president, in the chair. In her address of welcome, Mrs. Dwight reviewed the life of the Auxiliary, speaking of it as a child which until now had been doubting and uncertain but which is now strong and sturdy enough to stand upon its own feet.

Formed in 1917, the Auxiliary was faced with war work almost from its beginning, and accomplished much. The General Council early saw the necessity for local sections, and today, the New York, Anaconda, Butte, Canada, Denver, Los Angeles, Northern California, St. Louis, Utah and Washington, D. C., local sections have duly elected representatives on the Board of Directors of the Auxiliary. Mrs. Dwight emphasized, however, that:

1. Work by separate sections, while necessary to *their* life, does not constitute organization for the Auxiliary.

2. Work undertaken by the whole Auxiliary can be the means of bringing about a strong organization.

3. Such work must be national in character and continuous in operation.

Mrs. Dwight reported that the Council, which hereafter is to be called the Board of Directors, has held nine regular meetings and one special meeting. Mrs. Eilers, the treasurer, reported a balance of $683.61 on hand Feb. 1, 1922.

Digitized by Google

Mrs. Sidney J. Jennings, chairman of the Executive Committee of the Educational Fund, reported that the contributions to the fund for 1921 amounted to $1358.50, of which 25 per cent. is invested in a permanent endowment fund for engineering education. If the Auxiliary desires to appoint a beneficiary each year for a four-year course it will be necessary to secure a larger number of contributors.

Mrs. Jennings also mentioned the scholarship offered by Columbia University which was described in the February number of MINING AND METALLURGY, pp. 3 and 78. Mrs. Huntoon, treasurer of the Educational Fund, reported a balance of $2200.61 on hand on Feb. 21, 1922.

Mrs. Hoover, chairman of the Membership Committee, reported that 2200 cards of invitation to join the Woman's Auxiliary had been sent out and that a membership list was published on Jan. 1, 1922 and 1068 copies were mailed to members of the Auxiliary.

Mrs. F. F. Sharpless, chairman of the Press Committee, asked for regular and full reports of the work of the local sections.

The Committee on Revision of the By-laws, Mrs. W. Y. Westervelt chairman, reported that few changes were necessary, it being rather the work of the committee to amplify certain points and to correlate and make more available for use certain others—also especially to provide for the Educational Fund Committee which has become so important a branch of the work.

The local section reports were read, either by the women acting as proxies, or by members of the sections.

Mrs. J. B. Tyrrell, of Toronto, read the report of the Toronto Branch of the Association of Women of the Mining Industry of Canada, which was organized on Feb. 28, 1921, as the result of a suggested section of the Woman's Auxiliary to the A. I. M. E. in Canada. There was a general feeling that the woman's organization in Canada should be connected with the Canadian Institute of Mining and Metallurgy, rather than with the A. I. M. E., and also that something a little broader than the Woman's Auxiliary was needed, broad enough to include all women connected with the mining industry in any way.

The Association of Women of the Mining Industry of Canada has a three-fold object: to promote social intercourse among the women of the mining industry; to render service to all connected with the industry; and to encourage coöperation in work for the benefit of the community and the country at large in all that pertains to the interests of the industry.

The Chicago Section, through Mrs. Luther V. Rice, its chairman, and the Colorado Section, of which Mrs. Leonard is director, reported active interest and regular attendance at meetings.

The St. Louis Section, Mrs. Glasgow, director, has held three successful meetings during the year. Mrs. Newton R. Wilson, the treasurer of this section, has made a gift of $2900 for a scholarship at the School of Mines at Rolla, Mo., in the name of the St. Louis Section of the Woman's Auxiliary.

The Anaconda Section, Mrs. F. S. Adams, director, has expended $1929.07 in supplying milk to needy children and has raised money by dues, donations, teas and drives to contribute to the Educational Fund of the Woman's Auxiliary, the Montana Orphans' Home at Helena, the Anaconda Salvation Army Christmas Dinner Fund. The section helped to prepare the Municipal Christmas tree and made donations of gifts for 2000 children.

The Butte Section, Mrs. H. T. Mann, director, has contributed to the national organization, to the 1921 Hoover Fund, to the Charity Fund of the Neighborhood Committee, to the Auxiliary Educational Fund, and to the National Relief Council; a total of $222.90. The Butte Section has conducted a kindergarten in the public school of the foreign district, and a sewing school for girls. The section has found and taken care of a number of needy persons. Funds are being raised through social gatherings, but the chief funds for charitable work in Butte are provided from a Community Chest, each man having work in Butte contributing one day's pay per month. For each dollar donated by individuals the mining companies are donating a dollar and a half. The total fund has amounted to more than $50,000. The members of the Butte Section are working with the board of investigators and distributors of these funds.

Mrs. D. M. Liddell reported that the New York Section has done some work for engineers in the Fox Hills Hospital and various members have worked at the Service Clubs for ex-service men. The section has contributed $126 to the Educational Fund.

The Northern California Section was reorganized on Jan. 27, 1922, and is to be known as the San Francisco Section. Mrs. Edmund Jüssen is director.

Mrs. Philip Wiseman, director, made a very full report of the work of the Los Angeles Section. The monthly meetings were carried throughout the year, with the exception of July and August which were combined and celebrated by a picnic at Santa Monica. Talks have been given by members of the section, on mining districts in Africa, South America, Alaska, Mexico, Burmah, Russia and New Zealand.

Early in the spring the section answered a call from the Red Cross for garments for the Near East Relief; 195 new garments were made and enough good, useful, second-hand ones, donated by members, brought the contributions up to 300 garments. This section pledged $150 to the Educational Fund.

Mrs. R. C. Gemmell, director, and Mrs. Edward R. Zalinski, secretary, reported that the Utah Section is broadening. The Vacation Fund sends one or two working girls to the mountains during July and August. Last summer the members made children's garments for needy families in the camp at Bingham. An

Digitized by Google

entertainment is given each year to provide a subscription for the Educational Fund.

The Washington Section has not yet specialized in any work but has lent a helping hand to many. One of the members obtained a scholarship in geology for a young Russian stranded in this country. The section outfitted him and gave him a check for one hundred dollars. At Christmas, the section sent a donation to the Anaconda Section, and distributed clothing to the poor in Washington through the agency of the Juvenile Court. The secretary of the section, Mrs. Mulliken, wishes to establish a circulating library among mining camps, and already has nearly a hundred books. This section has also contributed to the Educational Fund.

After the section reports were completed, a vote of thanks was extended to Mr. and Mrs. Ludlow for their reception to the members of the Auxiliary and their guests, at the Ambassador Hotel on Feb. 20. A vote of thanks was also extended to Mrs. Barron for the luncheon and card party given the members of the Auxiliary who visited her home on Feb. 21.

The tellers reported the following elections for the year 1922: president, Mrs. H. W. Hardinge; first vice-president, Mrs. H. P. Henderson; second vice-president, Mrs. J. A. Church, Jr.; third vice-president, Mrs. W. Y. Westervelt; secretary, Mrs. J. V. W. Reynders; treasurer, Mrs. Karl Eilers.

At the afternoon session, Alexander Black entertained the Auxiliary by a short speech on the subject of "The Latest Thing."

On the other days of the annual meeting, the ladies shared the general entertainments provided for members of the Institute. On Monday morning, visiting ladies were shown some of the interesting sights of the city, and on Monday evening they enjoyed a theater party, while the Institute members were indulging in a smoker.

# Increase of Membership Department

**Total membership as of March 11, 1922, is 10,174**

APPLICATIONS FOR MEMBERSHIP.—The Institute desires to extend its privileges to every person to whom it can be of service. On the other hand, it is not desirable that persons should be admitted to membership in classes for which they are not qualified. Members of the Institute can be of great service if they will make a practice of glancing through the list of applicants and promptly notifying the Committee on Membership, or the Secretary of the Institute, of any person whom they think should not be classified in accordance with the list given.

The following persons have been proposed during the period Feb. 18 to March 20, 1922, for election as members of the Institute. Their names are published for the information of Members and Associates, from whom the Committee on Membership earnestly invites confidential communications, favorable or unfavorable, concerning these candidates. A sufficient period (varying in the discretion of the Committee, according to the residence of the candidate) will be allowed for the reception of such communications, before any action upon these names by the Committee. After the lapse of this period, the Committee will recommend action by the Board of Directors, which has the power of final election.

## Candidates for Membership

Members

**1—George Huntington Clark,** Birmingham, Ala.
Present position: Consulting Engineer, Assistant to State Geologist, Alabama Geological Survey.
Proposers: W. R. Crane, W. J. Penhallegon, T. H. Aldrich.

**2—Murray Nicholas Colman,** Atolia, Cal.
Present position—1921 to date: Metallurgist, California Rand Silver, Inc.
Proposers: Abbot A. Hanks, F. W. Bradley, David Atkins.

**3—E. F. Coste,** Dallas, Texas.
Present position: Manager, Eugene Coste and Co., Petroleum Engineers and Geologists.
Proposers: Eugene Coste, David White, David T. Day.

**4—Charles Prosper Dampman,** Philadelphia, Pa.
Present position: Supervisor, Fuel Conservation, Ph ladelphia and Reading System.
Proposers: S. M. Vauclain, D. B. Wentz, L. H. Taylor, Jr.

**5—Ira F. Davis,** Dorothy, W. Va.
Present position—1920 to date: General Manager, Fuel Mine Operations, Cleveland and Ohio Railway Co., Richmond, Va.
Proposers: William N. Page, Charles E. Krebs, James M. Clark, Carl Scholz.

**6—Somerville H. Eastment,** Philipsburg, Pa.
Present position—1920 to date: General Superintendent, Cedar Hill Coal Mining Co., Caswin Coal Mining Co., Brighton Coal Mining Co., Osceola Mills, Pa.
Proposers: Hugh Archbald, G. F. Dunkle, Richard H. Vail.

**7—Glenn G. Gentry,** Aspen, Colo.
Present position—1921 to date: Mill Superintendent, Silver Mines Co. of America.
Proposers: Stuart Croasdale, J. T. Boyd, Lewis G. Rowand.

**8—Carlos Edmund Holley,** Mancelona, Mich.
Present position—1920 to date: Mechanical Engineer for Autrim Iron Co.
Proposers: F. W. McNair, W. E. McRandle, J. B. Cunningham.

**9—William K. Kirby,** Golden, Colo.
Present position: Professor of Petroleum Engineering, Colorado School of Mines.
Proposers: J. C. Roberts, Lester S. Grant, Victor C. Alderson.

**10—Irvine Meredith Marshall,** Iron Mountain, Mo.
Present position—1921 to date: Mining Engineer, Iron Mountain Co.
Proposers: T. J. Mateer, S. D. Robinson, R. F. Taylor.

Digitized by Google

**11—William Rutherford Minds,** Ramey, Pa.
Present position—1894 to date: Superintendent, Bulah Coal Mining Co., Ramey, Pa. and New York, N. Y. Bulah Shaft Co., Ramey, Pa. (all affiliated).
Proposers: J. S. Sommerville, W. A. Jones, H. H. Morris.

**12—Russell S. Mitchell,** East Brady, Pa.
Present position: Superintendent, Kaylor Mines, Pittsburgh Limestone Co.
Proposers: Ralph E. Larry, V. M. Frey, Joseph T. Singewald, Jr.

**13—Willard F. Rhodes,** Los Angeles, Cal.
Present position—1921 to date: Associated with T. E. Mitchell in concrete research work and construction.
Proposers: T. E. Mitchell, M. W. Bacon, Harry V. Croll.

**14—William Roy Ridge,** Santa Monica, Cal.
Present position: Non-active in mining, developing oil lands in Louisiana.
Proposers: Thomas Warner, W. A. Newman, H. C. Morris.

**15—John Clark Ross,** Tulsa, Okla.
Present position—1920 to date: Geologist, Twin State Oil Co.
Proposers: Walter L. Dobie, R. S. McFarland, L. Murray Neumann.

**16—Ernest Henry Somerset Sampson,** Goyllarisquisga, Peru, S. A.
Present position—1920 to date: Coal Mine Survey, Cerro de Pasco Copper Corpn., Coal Mining Department.
Proposers: R. H. Allport, F. W. Collins, M. McDermid.
Endorsed by: The Institution of Mining and Metallurgy.

**17—Duncan Smith,** Bruxelles, Belgium.
Present position—1914 to date: Head of Mission for Exploration and Operation in Belgian Congo.
Proposers: C. A. Burdick, S. H. Ball, E. W. Engelmann.

**18—Harry Sordy,** Merlin, Ore.
Present position—1921 to date: Superintendent, Almeda Mines Co.
Proposers: Carl N. Anderson, Alva H. Gunnell, Henry M. Parks.

**19—Henricus Johannes Stander,** Wilmington, Del.
Present position: Flotation Engineer in charge of liquid products, Hercules Powder Co.
Proposers: Charles F. Willis, G. M. Butler, T. G. Chapman

**20—Edgar G. Willrich,** Tulsa, Okla.
Present position: Consulting Practice, Member of firm Cochrane, Willrich and Johnson.
Proposers: Victor H. Cochrane, John M. Lovejoy, R. S. McFarland.

**21—Deane Jackson Wolff,** Wichita, Kansas.
Present position—1920 to date: Geologist, National Refining Co., Cleveland, O.
Proposers: Herman J. Allen, Marvin Lee, Frank Carney.

### Associates

**22—Cunningham Le Roy Griffith,** Tampico, Mexico.
Present position—1920 to date: Geologist, La Espuela Oil Co., S. A.
Proposers: A. N. Winchell, E. F. Bean, H. R. Aldrich.

**23—George M. Humphrey,** Cleveland, O.
Present position: Partner, M. A. Hanna & Co.
Proposers: H. S. Stebbins, L. E. Dunham, C. N. Hickok.

**24—J. Everts Lamar,** Urbana, Ill.
Present position: Assistant Geologist, Illinois State Geological Survey.
Proposers: F. W. DeWolf, Harold E. Culver, James H. Hance.

**25—Crispin Oglebay,** Cleveland, O.
Present position: Chairman of the Board, Ferro Foundry & Machine Co.; General Manager, Oglebay Norton & Co., Agents.
Proposers: R. C. Allen, P. S. Williams, W. O. Hotchkiss.

**26—Howard Peck Smith,** Leonia, N. J.
Present position: Assistant Mechanical Engineer, Joseph Dixon Crucible Co., Jersey City, N. J.
Proposers: A. L. Haasis, Alex. C. Humphreys, Carl B. Peters.

**27—William Ambrose Ward,** Tampico, Mexico.
Present position: General Manager, English Oil Co., S. A. of Tampico.
Proposers: Rex Townsend, Paul Weaver, K. C. Stadtmueller.

### Junior Associates

**28—Claude Allen,** Butte, Mont.
Student, State School of Mines, Butte, Mont.
Proposers: Earl B. Young, Horace T. Mann, Theodore Simons.

**29—Clifton Thorne Barker,** Excelsior, Minn.
Student, Minnesota School of Mines.
Proposers: Peter Christianson, Walter H. Parker, W. R. Appleby.

**30—August F. Beck,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: R. J. Grant, James Underhill, J. C. Robert.

**31—Paul Frederick Boswell,** Stanford University, Cal.
Student, Stanford University.
Proposers: W. F. Dietrich, Theodore J. Hoover, Welton J. Crook.

**32—Isaac Griffith Brown,** State College, Pa.
Student, Pennsylvania State College.
Proposers: D. F. McFarland, William R. Chedsey, E. S. Moore.

**33—John Hale Clopton,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, Lester S. Grant, F. D. Aller.

**34—Richard Hudson Clough,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, Victor C. Alderson, Lester S. Grant.

**35—William Phillips Crawford,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, Lester S. Grant, F. M. VanTuyl.

**36—Frederick A. Dencer,** Champaign, Ill.
Student, University of Illinois.
Proposers: Ray W. Arms, A. E. Drucker, H. H. Stoek, Arthur J. Hoskin.

**37—Cecil Drake,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, Lester S. Grant, Victor C. Alderson.

**38—Timothy Holland Driscoll,** Butte, Mont.
Student, Montana State School of Mines.
Proposers: Theo. Simons, H. T. Mann, A. E. Adami.

**39—William Godwin,** Pinckneyville, Ill.
Student, Missouri School of Mines, Rolla, Mo.
Proposers: C. R. Forbes, C. L. Dake, J. R. Guiteras.

**40—Robert J. Hendricks,** Wallace, Idaho.
Student, University of Washington.
Proposers: Rush J. White, Fred W. Callaway, L. K. Armstrong, John C. Semple.

**41—Arthur L. Herman,** Bethlehem, Pa.
Student, Lehigh University.
Proposers: G. A. Roush, Allison Butts, A. Henry Fretz.

**42—James Edwin Jewell,** Kansas City, Mo.
Student, Missouri School of Mines.
Proposers: C. L. Dake, C. R. Forbes, J. R. Guiteras.

**43—Byron Albert Chapman Johnston,** Bethlehem, Pa.
Student, Lehigh University.
Proposers: Howard Eckfeldt, Benjamin L. Miller, H. B. Pulsifer.

**44—Walter Richard Landwehr,** Butte, Mont.
Student, Montana State School of Mines.
Proposers: Horace T. Mann, Theodore Simons, A. E. Adami.

**45—William Norman McBride,** State College, Pa.
Student, Pennsylvania State College.
Proposers: D. F. McFarland, William R. Chedsey, E. S. Moore.

**46—John Upton McFadden,** Philadelphia, Pa.
Student, University of Pittsburgh.
Proposers: H. B. Meller, E. G. Hill, Robert M. Black.

**47—William Carlton McKenzie, Jr.,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, T. M. VanTuyl, J. J. Lillie.

**48—Charles Bayard Mitchell, 2nd,** Woodbury, N. J.
Student, Lehigh University.
Proposers: Howard Eckfeldt, Benjamin L. Miller, Augustus Henry Fretz.

**49—Gregg M. Moga,** St. Paul, Minn.
Student, Minnesota School of Mines.
Proposers: W. R. Appleby, E. H. Comstock, Walter H. Parker.

**50—James Jackson Naughton,** Butte, Mont.
Student, Montana State School of Mines.
Proposers: Horace T. Mann, A. E. Adami, Earl B. Young.

**51—Charles William Nelson,** Pittsburgh, Pa.
Student, Carnegie Institute of Technology.
Proposers: Charles R. Fettke, Edward Steidle, Robert Z. Virgin.

Digitized by Google

**52—John Wilfred Patterson,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, F. M. Van Tuyl, J. J. Lillie.

**53—John B. Robinson,** Bethlehem, Pa.
Student, Lehigh University.
Proposers: Howard Eckfeldt, H. B. Pulsifer, Benjamin L. Miller.

**54—Joe S. Roper,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, Lester S. Grant, F. M. Van Tuyl.

**55—Sidney E. Ross,** Golden, Colo.
Student, Colorado School of Mines.
Proposers: J. C. Roberts, Lester S. Grant, Victor C. Alderson.

**56—Edward Patrick Shea,** Butte, Mont.
Student, Montana State School of Mines.
Proposers: H. T. Mann, Theo. Simons, A. E. Adami.

**57—Thomas C. Smith,** State College, Pa.
Student, Pennsylvania State College.
Proposers: Everett W. Smith, A. M. Rodgers, D. F. McFarland.

**58—Thomas Hodgson Stubbs,** West Chester, Pa.
Student, Massachusetts Institute of Technology.
Proposers: Charles E. Locke, Carle R. Hayward, Edward E. Bugbee.

**59—Donald Samuel Tedford,** Rolla, Mo.
Student, Missouri School of Mines.
Proposers: C. R. Forbes, J. R. Guiteras, C. L. Dake.

**60—Victor Theodore Thoeni,** Wykoff, Minn.
Student, Minnesota School of Mines.
Proposers: W. R. Appleby, E. H. Comstock, Walter H. Parker.

**61—Frederick Henry Villaume,** New York, N. Y.
Student, School of Mines, Columbia University.
Proposers: Robert Peele, R. M. Raymond, E. J. Hall.

**62—Paul Franklin White,** State College, Pa.
Student, Pennsylvania State College.
Proposers: William R. Chedsey, E. S. Moore, D. F. McFarland.

**63—J. Byron Wilson,** Minneapolis, Minn.
Student, Minnesota School of Mines.
Proposers: W. R. Appleby, E. H. Comstock, Walter H. Parker.

**64—Lyall Westley Zickrick,** Seattle, Wash.
Student, University of Washington.
Proposers: Joseph Daniels, Milnor Roberts, C. R. Corey.

**Change of Status—Associate to Member**

**65—Leopoldo Alcaraz Faustino,** Washington, D. C.
Present position—1921 to date: Assistant Chief, Division of Mines, Bureau of Science, Manila, P. I.
Proposers: William J. McCaughey, D. J. Demorest, H. E. Nold.

**66—Richard Raymond Smith,** Pulacayo, Bolivia, S. A.
Present position: Assistant Chief Engineer, Compañia Huanchaca.
Proposers: Roger T. Pelton, Harry M. Ziesemer, Le Roy B. Mitchell.

**67—Frederick Gale Tryon,** Washington, D. C.
Present position: Mineral Geographer, and Geologist, U. S. Geological Survey. In charge coal and coke statistics.
Proposers: George Otis Smith, G. F. Loughlin, David White.

**68—William Harrison Whittier,** Cartagena, Colombia, S. A.
Present position: Geologist for the Bataafsche Petroleum Maatschappy in South America.

**Change of Status—Junior Associate to Member**

**69—Enrique Juan Benoist,** Vina del Mar, Chile, S. A.
Present position: Engineer and Manager of Cia. Minera del Guanaco, Tal-Tal.
Proposers: Carl Edward David, Frank R. Van Horn, Zay Jeffries.

**70—Max Mueller Dixon,** Brooklyn, N. Y.
Present position: Geological work at Columbia University.
Proposers: R. J. Colony, J. F. Kemp, J. J. Galloway.

**71—John Stone Hoffmann,** Leon, Iowa.
Present position: Unemployed.
Proposers: Minard K. Shaler, Charles W. Boise, F. Van Brée.

**72—Dwight Lewis Sawyer,** Sneffels, Colo.
Present position—1921 to date: Geologist, Minas de Matalhambre, Province Pinar del Rio, Cuba.
Proposers: Charles A. Chase, Fred Carroll, James M. Hyde.

# Engineering Societies Library

**HARRISON W. CRAVER, Director**

The Engineering Societies Library, on the 13th floor of the Engineering Societies Building, 29 West 39th St., New York, contains approximately 150,000 volumes of engineering literature. It is open on week days, excepting holidays, from 9 a.m. to 10 p.m.

The Library offers, upon payment for the extra work required, to supply photoprints or translations of articles, make searches for information, prepare lists of references and suggest books on engineering subjects. The cost of searching is $2 an hour. Translations cost $6 and upwards per thousand words. Typewritten copies, $1 a thousand words. Photoprints, 11 by 14 in., cost $0.25.

In cases where the Library contains two copies of a book, one may be borrowed by any member. Transportation costs must be paid by the borrower.

The Library is at the service of every member. Those who cannot visit it may order searches, translations, copies, etc., by mail.

Address correspondence to the Director, Harrison W. Craver, 29 West 39th St, New York.

## Book Notices

**Automotive Repair.** By J. C. Wright. Vol. 1. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 530 pp., illus., diagrs., 9 × 6 in., cloth, $3.50.

For the repairman or owner who is expected to make general repairs and keep a car fit for operation. One hundred and eighteen jobs are given, with complete instructions; divided into chassis, engine, electrical, body and radiator work and "trouble shooting." They cover 95 per cent. of the problems encountered. The second section of the book presents the theoretical and mechanical information required to understand the construction and operation of the automobile.

**Burning Liquid Fuel.** By William Newton Best. (Revised edition.) N. Y., U. P. C. Book Co., Inc., 1922. 341 pp., illus., diagrs., 9 × 6 in., cloth $4.

Revised and enlarged edition of Dr. Best's book, formerly entitled the "Science of Burning Liquid Fuel." A plain, straightforward summary of long practical experience in designing and erecting oil fuel installations. Specific information is given upon the use of liquid fuel in many industries and upon all the various forms of equipment. Drawings show how the equipment is applied to various purposes. The book discusses locomotive, stationary, marine and low-pressure boiler equipment; practice in foundries and forge shops; equipment for the sugar, copper, ceramic, cement, baking, candy and oil industries, etc.

**Chemistry of Colloids.** By W. W. Taylor. Second edition. Lond., Edward Arnold & Co.; N. Y., Longmans, Green and Co., 1921. 332 pp., diagrs., 7 × 5 in., cloth, $3.50.

Discusses the general properties of colloids, methods of preparation, absorption and applications of colloid chemistry in dyeing, tanning, sewage purification, biology, etc. Intended as a convenient textbook and to serve as a reference work for workers in other sciences who are interested in colloids.

Digitized by Google

**Coal Catalog, Combined with Coal-field Directory, for 1922.** Pittsburgh, Keystone Consolidated Publishing Co. 1350 pp., illus., 12 × 9 in., cloth, $10.

The first section discusses the geology of coal; the coal areas of the United States; the preparation, storage, sampling and composition of coal. It gives a table showing the fusibility of coal ash by states and seams, a list of coke ovens, a list of coal exchanges and pools with their mines, and a table of analyses of coal. Part 2 classifies coals according to rank, use and structure. Part 3 lists the mines of the country, by states, giving their situations, officers, equipments, output, etc.

**Deep Well Drilling.** By Walter H. Jeffery. Toledo, O., W. H. Jeffery Co., 1921. 531 pp., plates, illus., diagrs., tables, 9 × 6 in., cloth, $5.

Deals with the two methods generally used, the cable tool and the hydraulic rotary, including the building of the derrick, drilling, handling casing, fishing out tools and the completion of the well, according to the best practice of the day. Supplementary chapters deal with oil and gas geology, cost of drilling, strength of materials, laws relating to gas and oil wells and other general information of use to the driller.

**Étude Géométrique des Transformations Birationnelles et des Courbes Planes.** By Henri Malet. Paris, Gauthier-Villars et Cie, 1921. 259 pp., diagrs., 10 × 7 in., paper. 32 fr.

A study, by synthetic methods, of birational transformations and plane curves. It strives particularly to establish the first principles and to set forth precisely, in logical and geometrical fashion, the conditions under which the homographic correspondence of laws is based. The exposition of modern geometry is based on the methods of Chasles and Poncelet.

**Die Flussmetalle im Brückenbau.** By E. J. Albrecht. Leipzig, Wilhelm Engelmann, 1914. 56 pp., illus., 11 × 7 in., cloth. (Gift of the author.)

A concise history of the introduction of mild steel as a material for bridges, with some notes on the influence of steel on bridge design and construction. The introductory chapter gives an account of the development of iron making up to the introduction of the Bessemer and open-hearth processes. The second chapter records the introduction of steel bridges in different countries, the growth of testing methods and the use of alloy steels.

**The Foreman and His Job.** By Charles R. Allen. Phila. and Lond., J. B. Lippincott Co., 1922. 526 pp., 8 × 5 in., cloth, $3.50.

This book has grown from the experience of the author in organizing and conducting conferences of foremen, called to discuss matters that affect the efficiency of their work. It deals with the problems that confront the foreman and suggests proper ways to deal with them. The book is intended for foremen and other minor executives and also for organizers of foremen's conferences, who will find it a suggestive guide in arranging programs.

**Ingenieur-Mathematik.** By Heinz Egerer. Bd. 2. Berlin, Julius Springer, 1922. 713 pp., 9 × 6 in., cloth. 528 M.

The author has endeavored to present the subject in a manner that will give the engineer a thorough grounding in the branches that he will find useful in his work, and that will enable him to think and feel mathematically in later years, when most mathematical formulas are forgotten.

Volume 1, on algebra, analysis, etc., appeared several years ago. The present volume treats of differential and integral calculus, series, curves, maxima and minima. A third volume is in preparation.

**Hydroelectrical Engineering.** By Richard Muller. New York, G. E. Stechert & Co., 1921. 431 pp., diagrs., 10 × 7 in., cloth, $6.

A systematic exposition of those principles of hydraulic and electrical engineering which underly the design of hydroelectric plants. Intended for engineers engaged in designing and constructing plants or reporting on their commercial possibilities.

**Introduction to the Theory of Relativity.** By L. Bolton. N. Y., E. P. Dutton and Co., 1921. 177 pp., 8 × 5 in., cloth, $2.

This is, to a large extent, Mr. Bolton's essay on Relativity and Gravitation, which won the Eugene Higgins prize, extended to some twelve times its length. The book forms a simple introduction to the new general theory of mathematical physics, showing that this develops easily and naturally out of the search for a general mode of statement of physical laws. The author has bent his efforts specially to making the reader understand the general drift of the principle of relativity, to realize what it is all about.

**Management of Accumulators.** By Sir David Salomons, Ninth edition. Lond. and N. Y., Sir Isaac Pitman & Sons. Ltd. 178 pp., illus., 7 × 5 in., cloth. $3.

Earlier editions have appeared as the first volume of "Electric Light Installations and the Management of Accumulators." This edition gives a general survey of the construction, management and use of storage batteries, adapted to use by owners and users. Particular attention is given to the technique of charging and discharging, and to failures.

**Manufacture and Uses of Explosives.** By R. C. Farmer. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921, (Technical primer series.) 116 pp., diagrs., 6 × 4 in., cloth. $0.85.

Information on explosives is so scattered and so much concerned with the details of individual explosives that it is difficult to obtain a general view of the nature and functions of explosives. This book endeavors to provide this, dealing first briefly with the historical development of explosives, and then with the manufacture and use of those most used today. Includes a brief bibliography.

**Materials of Construction.** By Adelbert P. Mills. Second edition, edited by H. W. Hayward. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1922. 9 sections, illus., 9 × 6 in., cloth, $4.

A general textbook covering the manufacture, properties and uses of the common materials of construction, including plaster, lime, cement, clay products, metals, alloys, timber, rope and mechanical fabrics.

**Mineral Land Surveying.** By James Underhill. Third edition, revised N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1922. 237 pp., diagrs., 8 × 5 in., cloth, $3.50.

Describes the methods used at the present time in surveying and patenting mineral lands in the western states. Intended for mineral surveyors and students of mining engineering. Several additions have been made in this edition, especially in the treatment of the direct solar observation. The specimen field notes illustrating the requirements of the office of the United States Surveyor General for Colorado have been rewritten and represent present practice.

**Die Pressluftwerkzeuge.** By P. Iltis. Zweite, umgearbeitete auflage. Berlin, Vereinigung Wissenschaftlicher Verleger, 1921. (Sammlung Goschen.) 117 pp., illus., 6 × 4 in., cloth.

After a brief general and historical introduction, this little book treats of the application of compressed air to hammers, percussion drills, punching, stamping and riveting machinery, drills, hoists and blasting machines. Within its limits, a large amount of information is given on the practical uses of compressed air.

**Principles of Alternating Currents.** By Ralph R. Lawrence. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1922. (Electrical engineering texts.) 432 pp., 8 × 6 in., cloth, $4.

A textbook developed from notes on alternating currents used for several years at the Massachusetts Institute of Technology with the junior students in electrical engineering.

**Physique Élémentaire et Théories Modernes.** By J. Villey. Pt. 1. Molécules et atomes. Paris, Gauthier-Villars et Cie, 1921. 197 pp. 10 × 6 in., paper, 15 fr.

Less scholastic than usual textbooks and more suited for reading, in which the essential phenomena of physics are set forth and explained by the most modern theories. Attention is especially directed to those phenomena that have received industrial application. Intended for the general public as well as for use as a textbook.

**Protective Relays.**—By Victor H. Todd. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1922. 274 pp., illus., diagrs., 8 × 6 in., cloth, $2.50.

This book attempts to cover the subject from first principles to the protection of high-tension networks, in a manner suited to the needs of operators and testers with a fair knowledge of electricity, and also of designers.

**Rays of Positive Electricity, and Their Application to Chemical Analyses.** By Sir J. J. Thomson. Second edition. Lond. and N. Y., Longmans, Green and Co., 1921. (Monographs on physics.) 234 pp., illus., plates, 9 × 6 in., cloth, $5.25.

This work gives an account of the experiments on positive rays which have been made at the Cavendish Laboratory, together with accounts of researches

Digitized by Google

on the Doppler effect in positive rays and on anode rays. Special attention is given in this new edition to those properties of positive rays which seem to throw light on the structure of molecules and atoms and on chemical combination. This edition contains a considerable amount of new matter, both text and plates.

**Steam Boiler Maintenance.** By Reg. Clayton. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Pitman's technical primers.) 118 pp., diagrs., 6 × 4 in., cloth, $0.85.

This brief account of good practice is clearly written in language devoid of unnecessary technicalities, to show how breakdowns may be avoided and maintenance costs reduced by systematic supervision. It is not intended to be a guide for firemen so much as to show the weak spots in the apparatus and to lead to the discovery and remedying of incipient defects and malpractices.

**Sewerage and Sewage Disposal.** By Leonard Metcalf and H. P. Eddy. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1922. 598 pp., illus., diagrs., 9 × 6 in., cloth, $5.

Practically a one-volume abridgment of the three-volume treatise "American Sewerage Practice" published by these authors in 1914–15. Intended for class use in engineering schools, but reflects the viewpoint of the engineer, not the teacher, and presents the information that its authors believe young students should acquire before taking up work in the field of sewerage engineering.

**Short Course in the Testing of Electrical Machinery.** By J. H. Morecroft and F. W. Hehre. Fourth edition, revised and enlarged. N. Y., Van Nostrand Co., 1921. 220 pp., diagrs., 9 × 6 in., cloth, $3.

Prepared to meet the needs of students in mining, mechanical and civil engineering, who have not studied the theory of electrical machinery, and hence need a brief summary of it as preparation for laboratory work. Besides specific directions for the tests, a brief analysis of the characteristics of the machines is given. New material on batteries, illumination, measurement of electrical energy and other subjects of interest to engineers generally.

**System Building and Constructive Accounting.**—By Raymond D. Willard. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1922. 307 pp., forms, 9 × 6 in., cloth, $4.

A textbook for students of accounting, devoted to the design of systems for various lines of business. The book analyses a number of systems in use, and illustrates, by charts and forms, suitable methods for the necessary records.

**Theory of the Induction Coil.**—By E. Taylor-Jones. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. 217 pp., illus., 8 × 5 in., cloth, $3.50.

Until recently there has been much divergence of view as to the manner in which the high potential is generated at the secondary terminals of an induction coil when the primary current is interrupted, and it cannot be said even now that opinion on the subject is quite undivided. In this book an account is given of a theory of the action of induction coils first put forward by the author in 1909. The theory was originally intended to apply only to the case of an air-core induction coil having a condenser connected with its secondary terminals. Subsequent investigations have shown that it is also applicable to an ordinary induction coil.

**La Théorie de la Relativité et ses Applications à l'Astronomie.** By Émile Picard. Paris, Gauthier-Villars et Cie, 1922. 27 pp., paper.

The permanent secretary of the Académie des Sciences gives an interesting historical and critical sketch of the theory of relativity with reference to its astronomical applications.

**Valuation of American Timberlands.**—By K. W. Woodward. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 246 pp., maps, 9 × 6 in., cloth, $3.

Gives principal facts regarding timber resources of continental United States and its outlying territories, excepting Hawaii and the Canal Zone, in a form suited to the needs of investors, timber cruisers and students of forestry. Contains descriptions of the forest types of the country, and comparisons of their values.

**Die Wasserversorgung der Städte.**—By O. Smreker. Fünfte auflage. Leipzig, Wilhelm Engelmann, 1914. (Handbuch der Ingenieurwissenschaften. Teil 3. Der Wasserbau, Bd. 3.) 522 pp., illus., diagrs., tables, 10 × 7 in., cloth, 57 Mk.

This work forms the third of the twelve volumes upon hydraulic engineering which constitute the third section of the Handbuch der Ingenieurwissenschaften, and is concerned with municipal water supplies. Thoroughly revised. The arrangement follows the course of operations used in securing a water supply, discussing first the preliminary studies of the amount, quality and occurrence of the available sources, then the design of the plant in general. Succeeding chapters discuss the winning and purification of water, pumping and conveying, and the operation of water-works. Attention is directed toward general principles, rather than to the details of specific installations.

### Geological Reports

The following reports, in mimeographed form, have been received from the Bureau of Topographic and Geological Survey of Pennsylvania; George H. Ashley, State Geologist.

Effect of The War on the Price of Coal in Pennsylvania (Bulletin No 1). By George H. Ashley. 3 pp.
Oil and Gas in Southeast Pennsylvania (Bulletin No. 2). By George H. Ashley. 4 pp.
Development and Probable Life of Gas Pool at McKeesport, Pennsylvania (Bulletin No. 3). By George H. Ashley. 3 pp.
Decline of McKeesport Gas Pool (Bulletin No. 4). By George H. Ashley. 3 pp.
A High-grade Building Stone in Greene County (Bulletin No. 7). By George H. Ashley. 2 pp.
Gas Wells on Pollock Run, Westmoreland County, Pennsylvania (Bulletin No. 12). By J. French Robinson. 2 pp.
Future Sources of Power (Bulletin No 14). By George H. Ashley. 3 pp
Geology of Oil and Gas in Relation to Coal (Bulletin No. 16). By George H. Ashley. 6 pp.
Coal Beds in Cambria County, Pennsylvania (Bulletin No. 23). By J. D. Sisler, 13 pp.
Coal Beds in Greene County, Pennsylvania (Bulletin No 24). By J. D. Sisler. 6 pp.
Coal Reserves in Greene County, Pennsylvania (Bulletin No 25). By John F. Reese. 6 pp.

## Bureau of Standards Papers

HEREAFTER Technologic Papers of the Bureau of Standards will be grouped in volumes. Beginning with Technologic Paper No. 203, the paging will be consecutive in the series until 750 pages are reached.

A title page and index (issued separately) will be transmitted with the last Technologic Paper of each volume to those libraries or subscribers who receive the complete series.

Subscriptions can be placed for the series of Technologic Papers by sending written orders addressed "Superintendent of Documents, Government Printing Office, Washington, D. C.," and inclosing $1.25 to cover a sufficient number of the papers to make one volume ($2.50 is required if the publications are to be mailed to foreign countries). Separate numbers of the Technologic Papers may be purchased at nominal cost by sending to the same address. (Do not address orders with money to the Bureau of Standards or the Department of Commerce.)

It is no longer possible to complete all the sets from the beginning. The Superintendent of Documents maintains a sales stock which will help to complete back sets, and he reprints any publication for which there is sufficient demand.

Circular 24 contains a descriptive list of all Bureau of Standards publications issued since the establishment of the Bureau. An extended abstract shows clearly the nature of the subject matter and gives in many cases a brief summary of the result. This list will be distributed to applicants free of charge.

# Employment Service Bureau

Notices for this column are not acknowledged by letter. Notices received before the 15th of the month will appear in the next issue.

Correspondence relating to replies to advertisements returned to the Employment Bureau will be held in the Bureau for one month.

Positions of the Bureau are on file in the offices of the member societies of the Federated American Engineering Societies and with secretaries of A. I. M. E. local sections.

## Engineers Available

**Mining Engineer.**—1921 graduate desires position in metal mining. Twenty months in Marine Corps during war. At present employed in coal mining. Single. Age 23. IM–1555.

**Mining Geologist and Mechanical Engineer.**—Desires South American appointment, preferably Argentina, with petroleum concern. Single. Age 25. Speaks Spanish fluently. Available July 1, 1922. IM–1556.

**Foreman Heat Treatment.**—Sixteen years experience on armor plate gun forgings and all kinds of heavy forgings and castings, including erection and operation of many types of furnaces, research testing and experimental work. Age 32. IM–1557.

**Bituminous Coal Mine Executive** desires change. Superintendent, chief engineer, or general superintendent. Western Pennsylvania or north West Virginia preferred. Twenty years experience, seven as chief engineer and assistant general superintendent. Expert on control through cost accounting. IM–1558.

**Mining Engineer.**—Eight years experience in United States, Mexico and Orient in large and small metal mines as prospector, miner, sampler, engineer, shift boss. Age 30. Single. IM–1559.

**Superintendent or Research Metallurgist.**—Capable and experienced millman and research metallurgist desires position in either United States, Canada, or Mexico as superintendent or assistant superintendent of concentrating plant, or as metallurgist in charge of research. Thoroughly familiar with operation and testing of latest types of milling machinery, especially oil flotation, and capable of conducting and directing research along these lines. Speaks Spanish fluently. Single. IM–1560.

**Mining Engineer.**—Sixteen years experience in development, operation, and examination of mines in United States, Alaska, Mexico and Central America. Can get results under pioneer conditions. Prefers Spanish America but will go anywhere. Age 40. Married. IM–1561.

**Mining Engineer.**—Fifteen years practice in milling, cyaniding, flotation and placer mining, in progressive positions from assayer to mill superintendent, in Mexico, Central and South America. Latin America preferred, but will go anywhere. Fluent Spanish. Age 39. Married. IM–1562.

**Mining Engineer.**—Desires position as superintendent or mine engineer. West preferred. Married. Age 30. Competent assayer, accountant, mine surveyor. Ex-1st Lieut. Engineers. IM–1563.

**Mill and Smelter Draftsman.**—Three years with mining, milling and smelting machinery companies, sixteen years with mills and smelters. Age 37. Single. IM–1564.

**Two Technical Men,** one mining engineer and one metallurgist, the former knowing Nevada well, seek a grubstake for a prospecting campaign in Nevada. Both have several years experience and believe can successfully apply knowledge on this trip and acquire by location, option, purchase or lease meritorious mining properties. IM–1565.

**Designing and Construction Engineer.**—Twenty years experience, mining, milling and industrial plants. IM–1566.

**Metallurgical Engineer.**—Successful research and operating experience in iron and steel and non-ferrous alloys. IM–1567.

**Professor of Metallurgy** at large university, with both industrial and teaching experience in non-ferrous metallurgy, ore dressing and fuels, interested in change for next year. IM–1568.

**Mining Engineer.**—Experience: Miner, coal and metals; Lieut. Engineers overseas; oil geology; engineer copper mine; division engineer lead company; resident engineer and assistant superintendent coal company. Prefers connection with reliable consulting engineer in examination and development work. Moderate investment possible. Age 27. IM–1569.

**Mining Engineer.**—Eight years operating, testing, and metallurgical statistics in connection with milling. Crushing, fine grinding, gravity and flotation concentration of copper and lead-iron-zinc ores. Business training course. Southwest preferred. Married. Age 31. IM–1570.

**Metallurgist.**—Specialist in ore concentration desires position as testing engineer or mill superintendent with progressive concern. Experience in testing, hydrometallurgy, concentration, flotation, and in mill design, construction, operation, and management. Business education. IM–1571.

**Mining Engineer.**—Experience in mine engineering, mill operation and construction. Desires position as engineer or assistant superintendent in United States or Canada. Age 30. Married. IM–1572.

**Mining Engineer.**—Varied experience in mining, milling and engineering. Eight years with large corporation as superintendent of underground and surface operation; two years as chief engineer for well known manufacturers of mining machinery. IM–1573.

## Positions Open

**Field Engineer** or scouts to examine for marginal flux or gold-bearing silica. About June 1 to Oct. 1. Apply by letter, giving age, education and experience. Canada. V–384.

**Engineer** familiar with lode mining, milling and operation of small cyanide precipitation plant. An investment of $5000 will be necessary. Colombia, South America. V–393.

**Expert Furnace Designer and Operator** having broad experience in steel works design. Must also have executive experience and ability. V–406.

**Chief Engineer** for large American coal-mining property in British Columbia. Must be coal expert with 10 years experience. Apply by letter only. V–502.

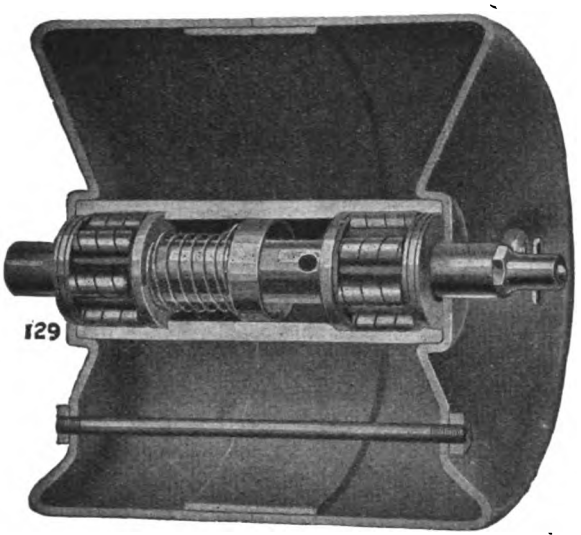
# Industrial News and Developments

Devoted to manufacturing and trade news of interest and value to the mining and metallurgical industry and invited from manufacturers and dealers. Scrutinized but not vouched for by the Institute.

## Pulleys on Belt Conveyors

SPECIAL features of the belt conveyors manufactured by the Stearns Conveyor Co., Cleveland, Ohio, are Hyatt Roller Bearing Idler Pulleys and Lubrication, illustrated in the accompanying cut. Each pulley is fitted with an Alemite lubricating plug, so that the carrier may be lubricated while the belt is running, by means of an Alemite grease gun. The lubricant passes through the hollow shafts into the grease chambers, which hold about six months' supply of grease. On the inclined pulleys,



gravity will furnish lubricant to the lower bearings, but in order to supply the upper bearings, the grease chambers are provided with automatic spring plungers.

Grease from the Alemite gun enters at 1, and comes out at 2, filling the grease reservoir and pressing back the plunger. It is impossible for dust to get into the bearings, as the grease works out through the bearings and forms protecting rings of grease at the only entrance to the bearings.

## Industrial Notes

**The Hardinge Company,** 120 Broadway, New York, announces the acquirement of the coal-washing equipment formerly supplied by the Coal Washing Equipment Co. of Pottsville, Pa. This consists mainly of the James Automatic Balanced Jig, which has been installed in a number of anthracite and bituminous collieries for reducing the sulfur and non-combustible content of coals ranging in sizes from ¼ to 4 in. Another device which has shown surprisingly good results is a combination of pulsating classifier and table capable of lowering the sulfur and ash content of slack sizes of coals, and also the washing of river coals and anthracite culm.* All of this equipment is now being made in the Hardinge Company shops.

Noel Cunningham, formerly connected with the Coal Washing Equipment Co., has been placed in charge of this new department of the Hardinge Company.

**Cement-Gun Construction Co.,** Chicago, Ill., announces that C. L. Dewey, who was associated with Carl Akeley in the invention and development of the cement-gun, and who has done extensive cement-gun contract work under the names of the Dewey Cement-Gun Co. and the Traylor-Dewey Contracting Co. of Allentown, Pa., has joined the forces of the Cement-Gun Construction Co. He will devote his time exclusively to the development of cement-gun contract work.

**Wilson Welder & Metals Co.,** Inc., 132 King St., New York N. Y., announces the appointment of R. L. White as district manager in charge of the Detroit Office, 809 Kresge Bldg., Detroit, Mich.

## Trade Catalogs

**Combustion Engineering Corpn.,** Broad St., New York.—Folder on Type K Automatic Stoker for small plants.

Booklet on Lopulco Pulverized Fuel System for Locomotives. This is said to be the first comprehensive treatise on this adaptation of pulverized coal. Tells of pioneer work and results achieved and contains a number of informative test reports.

**Wellman-Seaver Morgan Co.,** Cleveland, Ohio.—Bulletin 71. Material Handling Equipment as Applied to the Copper Industry. Describes car dumpers, filling bridge, excavating bridge, and excavators.

**Brown Instrument Co.,** Philadelphia, Pa.—Folder on a New Brown High Resistance Pyrometer with two important improvements, *i.e.*, automatic cold junction compensation including means of zero adjustment.

**Cement-Gun Construction Co.,** 537 South Dearborn St., Chicago, Ill.—Gunite Book No. 7. Contains excellent reproductions of photographs illustrating work done within the past two years.

**Scientific Materials Co.,** Pittsburgh, Pa.—Booklet on equipment for examination and photography of the microstructure of metals. Booklet on latest improved American Model Brinell Hardness Testing Machine, with straight line motion depth measuring gage. Leaflet on F. & F. Optical Pyrometer for measuring temperatures from 1500° to 4000° F. (815° to 2200° C.).

**Hercules Powder Co.** Wilmington, Del.—Flotation Oil Booklet, giving complete specfications on all Hercules flotation reagents. The last chapter gives methods for testing oils for adulteration. This booklet, and one by H. J. Stander, which gives a brief survey of flotation, may be obtained without charge by writing to the Hercules Powder Co., Naval Stores Division.

**The Merrill Company,** 121 Second St., San Francisco, Cal.—Booklet of 83 pages, on Merco Processes and Products describing the Merrill Precipitation Process, the Crowe Vacuum-zinc Shavings Process, the Merrill Sluicing Clarifying Filter, the Merco-Nordstrom Plug Valve, and Merrillite.

**Jeffrey Mfg. Co.,** Columbus, Ohio.—Catalog 359. Jeffrey Single Roll Coal Crusher for reducing coal, bone, alum, salt and similar materials.

## EDITORIAL

### The Coal Strike

IN ANY consideration of the present strike of coal miners, discrimination should be made between the positions of the anthracite and bituminous miners. This discrimination will refer to the underlying conditions in the two branches of the industry which I outlined in my address at the joint meeting of the Institute and the Society in February last, *viz.*, the bituminous coal-mining industry is overdeveloped and overmanned, while the anthracite industry is not so. The anthracite miners are now out on strike without any just grievance; while the bituminous miners are the victims of conditions which give them grounds for complaint, although they neither understand what are those conditions nor are they proceeding in the right way to correct them.

The position of the anthracite miners is simple. Constituting a strongly unionized force in the production of an essential commodity, they are endeavoring to retain their war scale of wages at the expense of the public in general, which means at the expense of all other groups of workers. Their retention of an inflated wage scale for so long has been due to the exclusion of competition by a monopolistic labor union and the vicious system of long-time contracts between it and the mine operators. These influences have been powerful in retarding the deflation of the cost of living in general.

In the course of the present controversy, there is being promulgated, as a matter of course, all kinds of statistics that becloud the issue. There is no denial of the fact that the cost of anthracite coal to the consumer is very high; nor can there be any denial of that, for it is self-evident to everybody. The labor leaders claim, however, that this is because the operators pile on their profits and that reductions in price ought to be made out of them. We engineers know that there is no merit in that condition, but there is no use in discussing it for, after all, it is merely a begging of the

Digitized by Google

question. The real point at issue is more fundamental, and it is this: Up to 1920, and inclusive of that year, there was annually an increase in the national income until it became about double what it was in 1911–14; but in a general way this was only an increase in inflated dollars and not in quantity of production. The share of labor, expressed through wages, increased in the same way, in the same inflated dollars, but rather more in proportion; for labor's share in the total produce of industry rose from about 70 per cent. to upward of 75 per cent.

These statements are of economic fact as nearly as anything of their nature can be, for they follow the recent report of the National Bureau of Economic Research, in whose directorate the labor organizations are represented and to whose findings the labor representatives assented and concurred.

Since 1920, the business of the United States has experienced drastic deflation. The national income in terms of dollars in 1921 was very much less than in 1920 and probably the present rate is still lower. The anthracite coal miners have retained, however, and are now seeking to maintain, and even to increase, their own inflated scale of wages.

It is not merely the anthracite miners who have done this, but it is also substantially the accomplishment of every group of labor that is strongly unionized. Among the great groups of this class, generally speaking, there are besides the anthracite miners the railway men and the builders. In the broad division of the produce of industry, labor as a whole has already deprived property and management of more than its proper economic share and has done so at its own peril; but that is not a subject to be entered into here. The immediate consideration is this:

With a diminished national income and with nothing more possibly to be abstracted from the share of property and management, of what remains a few groups of labor can maintain their own income upon an inflated basis only at the expense of all other groups of workers, *i.e.*, the public in general. The distress of the farmers and the high degree of unemployment among factory workers are directly due to this.

The anthracite miners are merely a symbol of this broad issue. If they can maintain their position by virtue of their monoply of the labor of an essential industry, the other perfectly unionized groups can do the same thing and all hope for the readjustment to the conditions of normality which must be accomplished before we can look for a return of general prosperity must be abandoned. We should, then, simply have to face a new condition of economic life with grave portents of evil.

The anthracite operators therefore owe a great responsibility to the public in fighting this thing through to the end, and the public owes to itself the obligation of supporting the operators and putting up with such inconvenience as may ensue. I am not sure that either the operators or the public appreciate their responsibilities in the present juncture, and particularly the public which has the most directly at stake. If the public knows what this fight means, it will not let the operators consent to any compromise. I doubt whether the reductions in wages that the operators have proposed be sufficiently sweeping. Anyway, I feel sure that agreement with the unions upon any long-time contract, even for a year, is contrary to public policy. The very fact that the anthracite coal-mining industry is closely controlled both by the operators, who are few, and by the union, which is only one, makes it easily possible to effect a compromise between the two parties upon a wage scale running for a long time, a system which embodies the vicious principle of "cost, plus." The plain necessity is that the public must have cheap anthracite, must have it as cheaply as in 1914, or thereabouts, and must get it on that basis as quickly as possible. I should like to see the operators take the position of "No contract and open shop," and if things lead to the downfall of the union, let that be.

The situation in bituminous coal is different in many elements. The bituminous coal-mining industry is overbuilt, overmanned, is only partially unionized; and it is subject to the competition of foreign coal and also of petroleum. Anthracite mining is an industry that is subject to seasonal fluctuations but on the whole it functions fairly well. Not so with bituminous mining, which is not only subject to seasonal fluctuations, but also functions very badly. This has been the subject of much study, particularly by this Institute, which considered the question at length at its first meeting in 1920. Mr. Hoover, who opened the discussion, pronounced the correction of the evil to be solely an engineering problem, but I am inclined to think that that idea is only partially correct. The evil finds expression in the condition that the personnel attached to this industry habitually finds employment for only a small portion of the working days of the year. In this the workers find a just ground for complaint. Their own naive solution is to establish a 30-hour week, which would tend to equalize the opportunity to work. If, in addition thereto, everybody could draw the pay corresponding with a 48-hour week all would be happy. The trouble with this idea, of course, is that the public would have to pay a large body of men for doing nothing during a large portion of their time, which would be expressed in costly coal.

One of the reasons for the irregularity in the employment of bituminous coal miners is the variation in the demand for coal at different seasons of the year. The unsteadiness of the load factor that is thus put on the mines unbalances the railway car movements and thus troubles are intensified. The engineering solution of these difficulties is to interpolate storage reservoirs between production and consumption, whereby the mines may produce regularly and over-demands or under-demands may be adjusted by means of the reser-

Digitized by Google

voirs. Storage facilities necessitate a large capital outlay, however, and there must be adequate inducement for its provision, which the present economic system does not offer.

Underlying all of this, there is the purely economic condition of chronic overdevelopment of the industry. There are too many mines opened and staffed. All of them cannot sell coal to their maximum capacity or even to the needful capacity for efficiency in operation. This is well recognized and various remedies are proposed, such as modification of the Sherman law to permit pooling arrangements, state regulation, governmental control, etc. The best of these would be futile. The worst of them—nationalization—would be ruinous. The simple remedy is to remove restrictions and give play to the natural laws that will lead to the survival of the fittest. One of the restrictions to be removed is the union, with its general wage scales and its destructive influence upon efficiency. The United Mine Workers itself is one of the greatest factors in maintaining the deplorable state of affairs in the bituminous coal-mining industry.

Obviously, the true economic solution of the proper functioning of this industry is the concentration of production in those mines which can produce most efficiently. They should have such freedom in their operations as to permit them to make such reduction in price in times of slack demand as to induce people to provide intermediate storage capacity. Any hampering restrictions, either of labor unions or governmental interference, should be abolished. I do not think that there are any halfway measures between this program and the methods at present existing.

Such a program of economic freedom would lead to the extinguishment of a good deal of capital invested in the superfluous mines, but, as a matter of fact, it has already been economically extinguished although it may not yet have been written off. It would also mean the transfer of the superfluous coal miners to other industries, and there should be governmental assistance in bringing that about. Such work would be a true function of the Department of Labor.

There are at least two other needful things. One of these is the formation among the coal producers of an adequate statistical association, in order that they may keep themselves constantly informed as to how things stand. The other is improved legislation among the states for safeguarding the workmen against accidents. I believe that the United Mine Workers has been instrumental in bringing about the correction of some evils of that nature, and this is the only useful function that that organization has ever performed, so far as I am aware.

With the elimination of the small, inefficient producers, physical dangers also tend to disappear, for the large producer does not want to have accidents and takes measures to avert them. However, as a matter of policy this should not be left in the hands of the operators alone and the function is properly a matter for attention by the state under its police powers. The coal-mining states already have legislation looking toward that end but it should be made more effective and should be on the lines of the recommendations of the committee of consulting engineers of the U. S. Bureau of Mines, as given in *Bulletin* 75 thereof, which would fix responsibilities on the miners as well as on the operators and would make both parties subject to penalties.

I am well aware that these several measures would be resisted by the miners. The latter do not want to be subject to any penalties, not even when they relate to their own well-being as a class, and their union supports them in their spirit of disorderliness. Nor would the surplus of miners kindly consent to being transferred to other industries, for in spite of the popular opinion to the contrary, coal mining is not a particularly hazardous occupation and, in general, is rather pleasant. The coal miners want to be coal miners, but that is no reason why the nation should support more coal miners than it needs.

However, the present strike of the bituminous miners is not going to lead immediately to any such correctives as I have suggested. In its immediate issue the same questions of deflation are involved as pertain to the anthracite industry. The difference in the position of the two industries results simply in the anthracite workers having been able to keep their war scale of wages and get it for work done, while the bituminous miners have kept it, but only nominally; in other words, they have not been able to cash in because there has not been enough work for them. The work has gone to the non-union fields where the miners have been willing to accept less.

While the present contest is not going to result in any early correction of fundamental evils, the operators in this branch of the industry also owe it to the public not to make any concessions. American industries are bound to have cheaper coal. If there be any agreements with the miners they should be by districts only and in conformity with the conditions peculiar to each, and they should not be for any specified times. The check-off should be abolished. If the result should be disruption of the United Mine Workers, that would be both to the public interest and also to the interest of the miners themselves.

W. R. INGALLS.

---

## What's Wrong with Coal?

WE DIAGNOSE the industrial symptoms in impressive phrases, as "fluctuations of operation," "deficiencies of transportation," and intermittency of employment," and we express similarly our economic prescriptions for their cure by the phrases "stabilization of industry" and "elimina-

Digitized by Google

tion of waste." It all boils down, however, to the assertion that the soft-coal industry is in a diseased condition and the country therefore demands a plain answer to the plain question: "What's wrong with coal?"

The average citizen knows coal only by the price he pays for it and by the size of his ash-pile, and he knows that both are now too high. If he thinks a bit, he realizes that the high price includes a freight rate (surely much higher than before the war) and profits to retailer, jobber, and mine operator (all said to be higher than in former years) as well as the wages of miners (also said to be higher than ever before). All these items are subjects of controversy, but the chief fact back of the high price we pay for coal is that coal really costs more than it did in other days. That's what's wrong with coal; and our next question is "why?"

Irregular operation of our bituminous coal mines is the outstanding reason for excessive costs of mining. The short working year of the miner is bad enough but his short working day adds to the unproductivity, and even worse is the uncertainty of his work. Many other trades have seasonal periods of unemployment, yet the bituminous coal mines of the country, in their very best week, when they were working their hardest to meet a war-time demand, averaged less than 42 hours, and even in their poorest week of 1921 when the country-wide complaint was "No market," they averaged 16 hours of operation. So it is, that with the average bituminous mine open for work only 215 days in the average year and only 170 days last year, the soft-coal miner faces not only the certainty of enforced idleness, but also the uncertainty of telling when his idle days are to come. Absenteeism and loafing on the job are the natural products of such an environment.

It is only too plain, also, that irregular operation requires more mines and more mine workers, and thus involves a sad waste of capital investment and a sadder waste of man power. This excess of capital and of labor in the coal industry, employed but not kept busy, must both seek wages for idle time as well as for working time. The high cost of this inflation of mine capacity and of working force is properly charged against what the mines produce, however short the working year, and the coal consumer pays the score.

The consumer, moreover, can be charged with some responsibility for this excessive cost as well as with the high price itself. The cure for the bad conditions is partly in his hands, for a more regular demand for coal could not fail to result in a more regular operation of the mines. Storage of coal by the consumer must tend to equalize demand and thus to prevent those price flurries, when the market is in the hands of the sellers and the extravagant offers for coal incite the speculative activity of jobbers and operators and thus still further develop a business that is already overdeveloped; and the last state of the industry is worse than the first.

Irregular operation, traceable in large part to blind neglect of the coal producer by the coal consumer, is thus both the cause and the effect of a double inflation that is conservatively estimated at half a billion dollars of misplaced capital and a hundred thousand misplaced men. What other country could support such a spendthrift industry?

But if complete betterment of conditions is to be attained, the coal industry must be its own physician. Legislative panaceas applied externally can do little; the real remedy must be applied underground; the coal-mining industry is in dire need of engineering. Hugh Archbald, in his book just issued, "The Four Hour Day in Coal," a title that is in itself an indictment, has linked together the two words engineering and discontent, and has proved, I believe, that the one is the only cure for the other. The coal operator can find no alibi in the fact that the mine workers have never sought to increase their own efficiency, for, as Mr. Ludlow has said, the bituminous coal business has itself specialized on selling coal, not on mining it; and I am forced to suggest a further parallelism with the labor union, which likewise specializes on bargaining for high prices, for my observation has been that both mine owners and labor leaders employ more lawyers than engineers. Collective bargaining over wage scales or united opposition to public inquiry can not take the place of coöperative effort in raising mine efficiency.

The plain facts presented by Mr. Thacher at the discussion of this subject by this Institute in February, 1920, really constitute a serious charge of inefficient management in the work of the Illinois coal mines as contrasted with the work of the zinc mines in adjacent states, where the average miner handles many times the tonnage credited to the coal miner. That charge remains unanswered; but Mr. Archbald shows that the way to increase the output of the coal miner and thus to swell his real earnings is to organize properly the work both of the industry and of the individual mine, to have engineers distribute the work underground and provide adequate haulage, and thus to give the miner a chance to work continuously a full day and so to maintain a proper standard of living by large earnings rather than by a high wage rate. The world owes the coal miner a living only as he earns it—but he should have a better chance to earn it.

The matter with the nation's coal bill is that it includes too much unemployment and too little productive work, a too-high wage scale and too-low earnings, a shameful waste of human energy instead of a worthy exhibit of thrift in industry, widespread discontent with an uncertain job rather than the wholesome satisfaction a good workman takes in steady and productive employment. The social failure of the coal industry can be traced to economic defects, and the cure for these is engineering. The engineering work needed to make the American coal industry truly worthy of our country will not be spectacular like

Digitized by Google

bridge building or canal digging, nor need it await novel inventions or great discoveries in coal-mining methods. What engineering can do for the industry is already known, for we have today large coal mines well laid out and equipped with modern machinery which show in actual practice how we can better the business of mining coal. Our chief need in this business, as in some others, is merely to raise the average up to the best. Mines planned by engineers and managed by engineers can, with the aid of the coal-consuming public, come much nearer to giving the mine worker an actual opportunity to work eight hours a day and six days a week. Then the mine worker himself would have some control of his earnings. Cheaper coal and larger earnings are two ideals which can be attained by engineering after bargaining has utterly failed.

The reform of the coal business must be worked out mostly underground, but its economic and social results will be seen of men, not only in coal that the nation's industry can afford to buy but in mining towns of which the nation need not be ashamed.

GEORGE OTIS SMITH.

## One Aspect of the Bituminous-coal Problem

IN STUDYING the problem of supplying coal to the community, one of the first difficulties that appears is that there are too many coal mines and consequently too many men engaged in producing coal. In round figures, it is estimated that there are 7000 coal mines, employing about 600,000 men. It is probable that 4000 coal mines, employing 450,000 men, could supply all the coal that is required by the United States for its domestic consumption and its export trade, provided the demand for coal could be more evenly distributed throughout the year. It is not necessary, of course, to point out that the public has to pay for maintaining the equivalent of 150,000 men in idleness, who probably each receive an average of $1000 a year; making a total cost of $150,000,000 a year which is unnecessarily added to the price of coal. This amounts to more than 30 cents per ton at the mine, without taking into consideration other additions to costs due to this unsatisfactory state in the industry.

The regulations under the recently passed bill for the leasing of coal lands makes it obligatory on the lessor to develop his lease within a limited time and to produce a minimum of 50 tons per acre per year. During last year, I understand that 15 leases were granted and that 100 were applied for. The average number of acres of land under each lease was 1000. If all of the 100 leases applied for were granted, the minimum amount of coal that would be forced on the market would be 5,000,000 tons a year.

Most of these leases are for land in the Rocky Mountain and the Pacific Coast states. The production of these states in recent years has been about 40,000,000 tons. If the production of 5,000,000 tons a year is added to this with a potential capacity very much greater than the 5,000,000, it will tend to demoralize the coal business of that region still further.

It is one thing to point out a difficulty and quite a different thing to point out a remedy. The fundamental difficulty of the coal business seems apparent. The means for remedying this has occupied the minds of many thinkers for many years. A suggestion has been made which seems to deserve thought and discussion, in order to determine whether it will solve the difficulty or whether the remedy will be worse than the disease.

The first part of the suggestion is that no new leases should be granted on public lands except to an existing company which desires additional land in order to continue its operations or to a new claimant who could show at a hearing before the proper departmental officials that public necessity requires development of new coal land.

The second part of the suggestion is that the Interstate Commerce Commission should have the right to allocate coal cars to a reduced number of operators, sufficient in number so that if the mines were worked full time the public demand for coal would be supplied. If there were full-time work, the earnings of the miners would be adequate, living conditions would be bettered, and coal would be supplied at a minimum cost.

It may be objected that the proposed remedy is too bureaucratic and puts too much power in the hands of the Government departments and commissions. If it is agreed that the fundamental difficulty of the coal industry is that there are too many coal mines, it would appear that there are only two effective ways of limiting the number—by Government regulation or by consolidation. The public opinion of the United States as expressed in its anti-trust laws limits the extent to which consolidation can take place. Therefore, it seems to me desirable that the full extent of the advantages and disadvantages of Government regulation by which the number of coal producers could be limited should be explored to the fullest extent, to see if in this direction a way out cannot be found.

SIDNEY J. JENNINGS.

## Officers of the Institute

ELSEWHERE in this issue (p. 54) is a complete list of the officers of the Institute and chairmen of technical committees and local sections. This is the first list that has been published since the incoming of the new administration in February, and should be preserved for reference. Every member of every committee has been furnished with a complete list of the personnel of that committee and this information will be gladly transmitted to any member who desires it.

PERCY E. BARBOUR.

# Review of the Month

THE strike of the coal miners began on April 1, as had been expected, the entire force of unionized miners—both anthracite and bituminous—going out and making this the most widespread strike of record. Up to the present writing there has been no serious inconvenience to industry in general, the accumulated stocks of coal being large and the non-union mines having continued to make a substantial production. However, the union labor leaders, having concentrated their efforts toward inducing the non-union miners to go out also, met with some measure of success in certain fields and created a shortage of coking coal, which caused iron makers to bank a few furnaces.

The strike of textile workers in New England spread further. Here and there throughout the country there were sporadic troubles with the builders. Railway labor was the subject of continued palavers, which did not get anywhere. On the whole the events of April were in line with the forecast that this would be a year of labor troubles.

In domestic politics, the soldier bonus bill, having been passed by the House, went to committee consideration in the Senate. Public opposition to it manifestly waxed. On the floor of the Senate the tariff bill was under consideration and is drawing nigh to passage, without there being much consideration of its probable economic consequences. It is going to be a very high tariff and there is much in it that is equivalent to subsidizing small and normally unprofitable industries at the expense of the people as a whole.

Abroad affairs were more quiet, superficially at least, than they were in March. In Egypt, India and South Africa things calmed down, so far as we know, but in Ireland there was continued turmoil. The Irish, having won their freedom to the same degree as the Canadians, have entered upon violent quarrels among themselves, more over phrases than anything else, so far as we can see. Lloyd George obtained a spectacular vote of confidence from Parliament and thus postponed the exigency of a general election.

The great event of the month was, of course, the assembly of the conference at Genoa. This is noteworthy as being the first post-war meeting of all the nations of Europe and without there being any distinction between victors and vanquished. The announcement soon after the middle of the month that Russia and Germany had concluded a treaty between themselves produced a great deal of confusion in the conference, with the prospect that serious results would ensue.

In commerce and industry the situation in Europe remained about as it was, except in Spain where troubles increased. On the other hand, business in Great Britain experienced considerable improvement. Australia continued to meet with difficulties resulting from its labor regime. In the United States there was a certain swelling in activity, which has been talked about for more than it is worth. The explanation is, of course, the replenishing of stocks between the producer and consumer.

In general the increase in business activity, such as it is, reflects the replenishment of stocks of goods, the performance of necessary repair work (largely by the railways), increased building of locomotives and railway cars, a moderate increase in house building, and a considerable advance in automobile building. The last is not a good feature. The fundamentals of the situation remain quite unchanged.

This is not, however, the common opinion, which as expressed through the stock market is foreseeing a rapid recovery from business depression. There has been a wild bull market in which the prices of many industrial stocks have been elevated to relatively high figures, although the time when dividends may be expected from them is far distant. The ease in money, as reflected by low interest rates, does not indicate prosperity, but rather the reverse; but it does indicate the progress of liquidation. It is the absorption of new issues, not merely for refunding, that reflects prosperity, thrift and the use of its savings.

The prophyry copper mines resumed operation on April 1. Now all the copper producers of North America are in motion except United Verde. The copper market after rising to about 13¼ cents in March became quite weak and fell to about 12½ cents early in April, but has since rallied to about 12⅞ cents. Lead became strong, rising from 4.70 cents to 5¼ cents, this being ascribable to continued good demand for white lead, together with an improved demand for certain of the blue lead products, especially building supplies and storage battery material. Spelter also was a little stronger, responding to somewhat better buying by galvanizers and brassmakers, while the possibility of selling for export to Europe, whither some small supplies were actually contracted, was an upholding factor. The markets for pig iron and steel products became a little stronger as a consequence of the coal strike. On the whole, the month of April was encouraging for the metal industries, but with the exception of lead they are still far from a profitable basis.

# The Coal Crisis of 1922 and its Ultimate Solution

By EUGENE McAULIFFE
President, Union Colliery Co., St. Louis, Mo.

TWO years ago the American Institute of Mining and Metallurgical Engineers made a memorable contribution toward a better understanding of the problems that have for many years confronted the coal industry. Specific suggestions toward betterment were then advanced, certain of which were taken up, amplified and endorsed by men who were conscientiously interested in the work of lifting this great industry out of the morass it has lain in for years. Two certain suggestions then made—provision for seasonal variations in railroad freight rates that would tend to encourage the purchase and movement of coal during the low summer production period, and provision for the collection by the United States Government of all the facts surrounding the industry—were introduced in the form of legislation in the United States Senate by a member of that body, a man whose personal character, antecedents and business training put him above and beyond all suspicion of demagoguery; however, as the result of the insistent, vindictive opposition of the industry itself, these two bills, constructive in their nature, were buried under an avalanche of misrepresentation. Today, with all mines that employ union labor at a stand still, the work of stabilizing the industry is yet before us. As aptly stated by Herbert Hoover, in March, 1920, when he was president of the Institute;

> An engineering organization is particularly the body to undertake this work. It is an economic problem, an engineering problem within the ken of our experience; it is a problem that requires not only constructive thought but quantitative thought and wise social thought.
>
> The engineers of the United States occupy a position midway between capital and labor. They enter upon problems of this kind without prejudice either way, and they have that faculty of mind for quantitative thought, as distinguished from qualitative thought, that takes such problems as this out of the region of politics into the region of matter-of-fact solution.

## The Present Controversy

John L. Lewis is the president of the United Mine Workers of America and, as its chief spokesman, the public will, as a matter of justice, continue to read his presentations of the mine workers' case; likewise, statements of the accredited representatives of the coal operators' associations, that never have been and are not now unified, will be read by the people. Unfortunately, neither side presents all the facts; like the average court witness, each side tells the truth, but not the whole truth, and it is the whole truth that is necessary to the right solution of this vexatious problem.

Mr. Lewis has one talking point that he reiterates at every opportunity, *i.e.*, the failure of the operators in the so-called central competitive field to meet him prior to April 1, as provided for in the contract. What are the facts? At the opening hearing of the Bituminous Coal Commission, Jan. 12, 1920, Mr. Lewis said:

> I am advised, Mr. Chairman, that the United Mine Workers are here to assist the Bituminous Coal Commission in every proper and practical way to arrive at their conclusions, and to coöperate in every manner, and to submit our interests to the commission, without reservation, and shall abide by the judgment of the commission.

The majority and minority reports of the commission were handed to President Wilson on March 10, 1920, article *C* of Award (p. 53) reading: "That the agreement for which this award constitutes a basis shall take effect April 1, 1920; and continue in effect up to and including March 31, 1922."

This provision was later written into the four-state agreement and signed by the several state representatives of the United Mine Workers from Pennsylvania, Ohio, Indiana and Illinois. With the promulgation of the four-state agreement, it was "resolved that an Interstate Joint Conference be held prior to April 1, 1922," etc. On the failure to carry out the terms of this resolution, Mr. Lewis is attempting to build his case before the tribunal of public opinion; it is the hub around which his whole structure revolves. In presenting the existing situation to the 10,000 members of the Institute, any approach toward a partisan attitude must be excluded and all reference to Mr. Lewis must be looked upon as wholly impersonal; he is merely the guiding hand of the machine. The coal operators of Western Pennsylvania and Ohio made a strategic mistake in not meeting Mr. Lewis prior to April 1, 1922, but has Mr. Lewis forgotten that in July, 1920, the mine workers in Illinois and in portions of Indiana, Pennsylvania and Ohio (this same so-called Central Competitive field) struck, demanding a revision of the wage scale (of which the resolution providing for a joint meeting prior to April 1, 1922, was a part) and eventually returned to work under a new agreement which gave day men an increase of $1.50 per day effective Aug. 16, 1920? Has Mr. Lewis likewise forgotten that President Harding called him to Washington for

Digitized by Google

a conference which was held on Oct. 8, 1921, the purpose of the President, as well as of the Secretaries of Commerce and Labor, Mr. Hoover and Mr. Davis, that of arranging a meeting between the operators and the mine workers to the end that no interruption of production on April 1 should occur? This is the meeting which should have been held, the date sufficiently advanced to have made possible the avoidance of the then unnecessary, enforced and unseasonal storage of from forty to fifty million tons of coal. Mr. Lewis forgets that while the operators agreed to the call for the meeting, he and his associates refused to commit their organization to any prior understanding pending the anticipated National Convention which was held in February, where the 30-hour week and other things were demanded for the bituminous workers and an increase of $1 per day for shift men and 20 per cent. for contract men was demanded in the anthracite industry; likewise he is silent on the point that although the anthracite operators did actually meet the union in New York City, March 15 last, their mines went out on a strike April 1, with those of the bituminous operators who did not meet them. Mr. Lewis's attempt to use the failure of the Penn-Ohio operators to meet with him (after he had flouted the request of the President and his cabinet) under the terms of an agreement that he and his constituency did not hesitate to breach in November, 1919, and in July, 1920, is a mere smoke screen to hide the real situation. One substantial reason for the refusal of the eastern operators to meet [Mr. Lewis after his national convention had promulgated their unreasonable and impossible demands has not been given to the public, that is the certain knowledge that the officers of the mine-workers' union dare not hand their followers the revised wage scale that must come unless it carries with it that necessary concomitant, work. Both the operators and John L. Lewis know that the country is saturated with coal. Consumers began to buy in December, 1921. They bought and stored during the mild winter season, paying for much of the coal stored less than mine cost; they bought quietly, even insidiously, miners and operators alike believing that the reduced output of the mines was being used currently. For once, the consumer did not suffer panic and, as a matter of fact, the solution of what the lawyers call "the instant case" rests neither with Mr. Lewis nor with the operators.

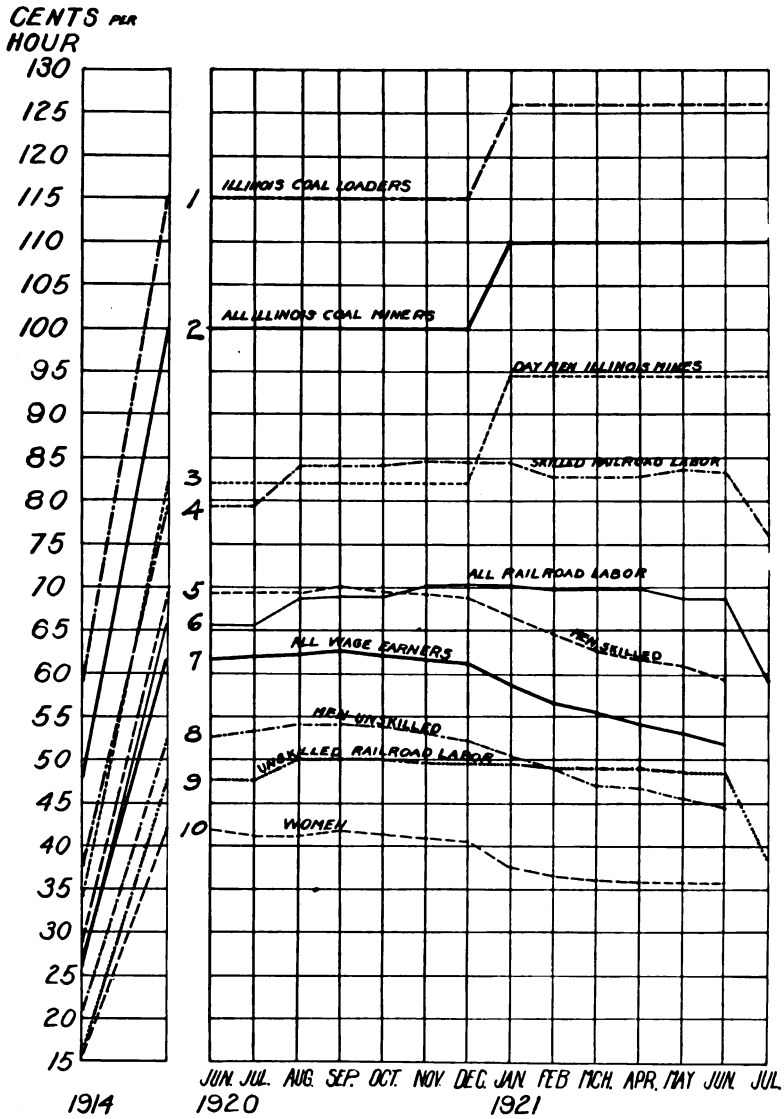

FIG. 1.—AVERAGE HOURLY EARNINGS VARIOUS LARGE INDUSTRIAL GROUPS, JULY, 1914 TO JULY, 1921.

Lines 1, 2 and 3 from official statistics Illinois Coal Operators Association; lines 4, 6 and 9 covering railroad labor, and lines 5, 7, 8 and 10 covering industrial plants, taken from Research Reports Nos. 45 and 46 of National Industrial Conference Board.

### THE REAL ISSUE

Mr. Lewis continuously dodges the real issue at stake; it has been and is still being dodged by other selfish and shortsighted men. This issue is one of the deflation of war and post-war prices. He is not the only character whose record is that of trying to hold out to the end. Perhaps he has in mind the story of that courageous but ill advised Frenchman, the last of Napoleon's Guard who, when in the closing hours of the battle of Waterloo was called upon by an English captain to surrender, gave as his answer one untranslatable word. Mr. Lewis stands today at the end of a blind entry; in front of him is the solid wall of economic facts, the only road to daylight is the one the farmers took two years ago, which the coal operators and the manufacturing industry took in the fall of 1920, and which the railroad employees whose aid he sought a few weeks ago have been treading for many weary months, with the end of their journey yet afar off. It is madness for the leaders of the four or five

Digitized by Google

hundred thousand mine workers, who under proper leadership will always ring true, to try to teach the pernicious belief that the coal industry is one in which

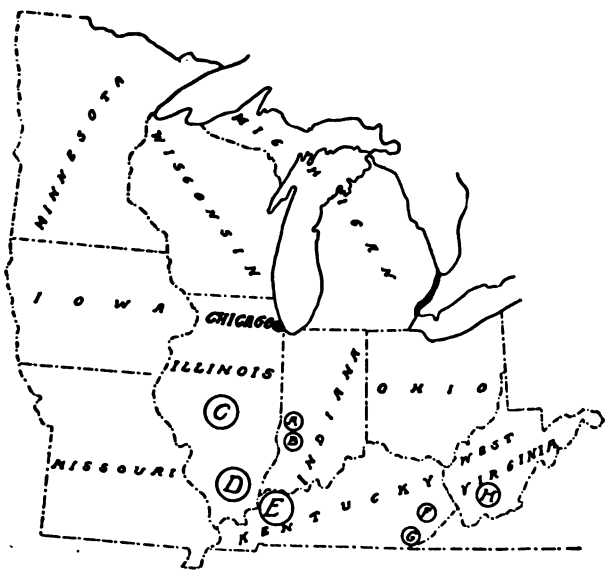

FIG. 2.—MAP SHOWING RELATIVE LOCATION OF EIGHT PRINCIPAL COAL FIELDS SHIPPING TO CHICAGO, THE WORLD'S GREATEST COAL MARKET.

the devotees can continue to occupy a pedestal apart from that of the mass of their fellow citizens.

## THE CONDITIONS SOUGHT

The mine workers in unionized territory seek not only to retain a war wage extorted from the consumers of coal in defiance of the findings of a governmental commission appointed to fix the wage, but they seek to increase it, and, through the medium of a shorter working period, continue to impose on the consumers of coal approximately 150,000 men who are not required by the industry. To do this they seek a unit wage so high as to make possible, by working three or four days per week, the gaining of sufficient to carry the excess number of men mentioned. The comparison of wages paid in the coal mines of Illinois, which are representative, and those paid in other lines of endeavor well expresses the rarified altitude into which the mine workers have lifted themselves (Fig. 1.). When it is recalled that the young man who operates a haulage locomotive in an Illinois mine receives $9.04 for a day's work while the locomotive engineer who drives the mammoth passenger locomotive of today, responding to every call, in any hour, any weather, receives $6; while the railroads cut off and dismissed during the 12-months period ending September, 1921, a total of 446,-550 employees, a force equal to the entire army of soft-coal workers; it is time to "stop, look and listen."

## NON-UNION COMPETITION

Much has been said in praise of the non-union miners located south of the Ohio and Potomac Rivers. During the strike of Nov. 1, 1919, when the mine workers challenged not alone the whole American people but their accredited governmental heads, the non-union mines kept the nation in fuel, at a great loss, however, attendant on the long rail haul required and the dislocation of the empty coal-car supply which resulted in car shortages and high prices throughout the greater part of 1920. Today these same mines are in many cases paying a wage rate below what the union mine worker terms a proper standard of living. This situation is fundamentally wrong and to the extent that the miners' union has created the condition, it is deserving of criticism.

As the situation stands today, the coal-mining investment of the nation is "half slave and half free." To create a similar division between the mine workers north and south of the line above mentioned is unsound. There is an American standard of living, and the opportunity to enjoy it is the rightful heritage of every good citizen and law-abiding alien among us. For months,

under the stress of a wholly artificial economic situation, many mines north of the rivers mentioned were closed down, others worked from 5 to 50 per cent. of full time, while the non-union mines south of the rivers undersold them in their natural markets, the nation taking up the difference in mine cost in the form of an increased transportation bill occasioned by the excess expenditure of the gross-ton miles required to transport the tonnage so diverted an undue distance. From the standpoint of all the people the end result lies in:

1. The closing down of properties and enforced idleness of the labor attached to same, north of the dividing line.

Digitized by Google

2. The stimulus toward the development of additional unnecessary mines with the extension of and additions to equipment of old mines, south of the dividing line.

3. The waste of labor, fuel, train and engine supplies, etc. employed in moving coal, a heavy commodity, an undue distance by the railroads and the dislocation of railroad equipment.

4. The arbitrary diverting of opportunity for labor from union to non-union fields with the enforced migration of union workers to non-union fields.

All of which tends to postpone the stabilization of this great industry.

cannot exist by the free and voluntary support of its own membership has no justifiable place in our social structure. The enforced membership and payment of dues such as exists here is slavery, no more, no less. The condition should be wiped out with the end of the present agreement.

### Collective Bargaining

I have expressed before this my belief in the theory of collective bargaining. I am in favor of unions soundly constructed and honestly administered. All unions should be forced to incorporate and should be

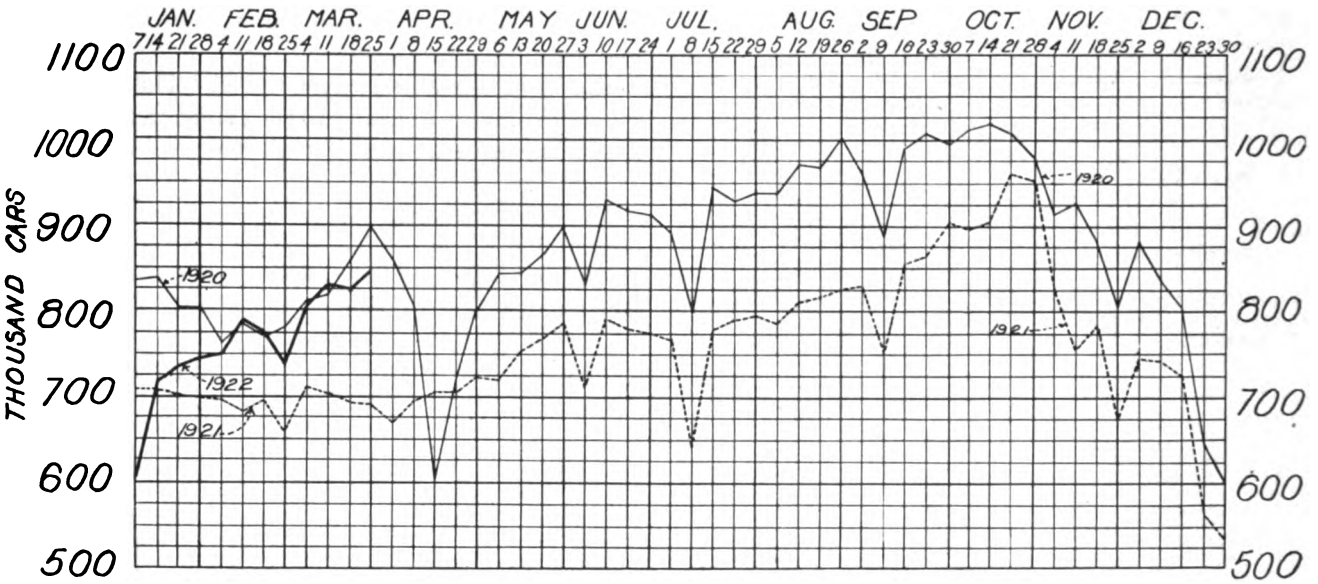

Fig. 4.—Revenue car loading years 1920, 1921 and first quarter 1922 compared. Compiled by American Railway Association.

The map (Fig. 2) with tables of distance from the natural sources of supply, as well as those thus artificially created, to the world's greatest coal market—Chicago—offers a clear visualization of the waste of transportation the taxpayers are paying through the railroad payroll.

### The Check-off

At the foundation of the abuses that surround the mine-workers' union lies the much discussed check-off. Years ago certain operators agreed to collect at the source certain special assessments levied for sick benefit and funeral purposes. From this modest beginning the abuse has grown until the tax levied on mine workers, and through them on the consumers of coal, runs into millions of dollars annually. This tax, running frequently above six cents per ton of coal produced, is used to build up and maintain the machine that in the fall of 1919 defied all three branches of our National Government, executive, judicial and legislative. The mine-workers' union is the only union in existence that requires the employer to collect its dues and assessments at the source. A union that

subject to all of the laws, rules and regulations that govern corporate or partnership holdings of capital goods or accumulated savings, including the payment of federal income and excess-profits taxes. All malicious interference with the operation of a mining property by its labor should be eliminated. A cross-section of the average mine committee will usually disclose the fact that the principal qualifications for membership are a lack of family ties, absence of home ownership or other property holdings, a plethora of unpaid bills and a blatant vociferous talking capacity. Rarely do you find a home owner, of whom there are many among the mine workers, on the "pit committee;" neither does a home owner care to hazard himself to the insult to which he is usually subjected when fair treatment and considerate action is advised.

### Mine Worker and Absenteeism

The industry is a vital and fundamental one, its workers should receive good, fair wages, but the problem of caring for the fluctuations in volume of business between years of activity and depression is one that cannot be cured by excessively high wage rates.

Digitized by Google

The wages paid mine workers today in the union fields runs from 100 to 250 per cent. above those paid in the non-union fields. One extreme represents an excessive wage that is strangling all industry, while the other suggests a wage too low to maintain even the most conscientious worker; neither condition one that will best serve the nation's welfare. I have a definite feeling that unduly depressed wages are even less defensible that those inordinately inflated. Whenever wages are considered, the offense of voluntary absenteeism from work exceeding 10 per cent., which is common to the mine worker, must not be forgotten.

Mine workers as a class absolutely refuse to recognize their responsibility to the industry. Absenteeism represents a condition that has grown up gradually; it is an uncontrolled privilege suffered by no other industry. The first duty imposed on the mine staff after starting time in the morning is that of seeking substitutes for men occupying what might be called "key" positions, motormen, tripriders, machinemen, etc. who are essential to the creation and movement of the tonnage which the loaders place in the pit cars. This situation tends to reduce the day's output, it increases the unit cost and multiplies the hazards attached to mining.

Under the contract, the mine worker cannot be approached on the question of absenteeism providing he reports on alternate days on which the mine works; that is to say, if he is absent Monday, he may return Tuesday, absenting himself on Wednesday and so on, this without even the formality of an excuse. The more flagrant cases, who stay out for several days in succession, will advance excuses based on trivial family affairs behind which the mine management cannot go. During periods of active work, 25 per cent. of absenteeism in some mines is not uncommon.

Whatever the measure of such action, get clearly in your mind that to obtain a given average output the entire plant investment, including underground development, mine machinery, track material, rolling stock, etc. must be increased and maintained in working condition in amount equivalent to the measure of absenteeism suffered. To this must be added the loss sustained from the indifferent services rendered in certain important positions, by loaders who resent being drafted for emergency service as motormen, machinemen, etc. What office, factory, or mill organization would tolerate the continued absence of 10 to 25 per cent. of its employees, without even the formality of notice? Further, and unlike any other form of unskilled labor, the loaders, who approximate 60 per cent. of the mine force, begin leaving the mine at the end of the fifth hour, continuing to straggle out thereafter. It is not probable that the working day of this class of labor runs on an average to exceed six and one half hours.

The annual turnover due to the migratory and shifting habits of mine workers represents an economic loss in excess of that suffered by any other form of industry. There are some splendid men in our mines; that is evidenced by the fact that approximately 35 per cent. of the men on the payroll earn 60 to 75 per cent. of the wages paid during each two-weeks period. This better element, however, is dominated and overrun by the irresponsible minority who vociferously exploit the "rights of labor."

### Discipline Within the Industry

A sound relation does not now and never will be created between the industry and its employees until the leaders of the union are compelled to cease all petty interference with the management of the mines. In no other industry does puerile interference and complaint reach the proportions that obtain in a coal mine. The men *per se* are not responsible. The trouble rests with the machine itself which has been built up on a foundation of money extorted from the workers in amounts so huge as to submerge leaders gifted with much greater poise than exists here. Given a mine wage approaching that paid other labor of equal skill and importance, and the competition between employers for labor insure the mine worker his just deserts, particularly when seconded by an enlightened public opinion.

### Magnitude of the Coal Industry

The nation holds three great outstanding lines of industrial endeavor: the railroads, the coal mines and the steel industry. Steel is frequently referred to as the barometer of trade. The steel and iron industry consumes approximately 100,000,000 tons of coal

Digitized by Google

annually. The steel-making fuel movement in the form of coal and coke, as well as that of the finished product, makes heavy demand on the transportation resources of the railroads, so heavy it can be well said that the three are interdependent and related industries. The comparison and growth in net tons set forth in Fig. 3 shows clearly how far coal and steel have traveled together in the past three decades.

### Settlement of the Instant Case

In a preceding paragraph the statement is made that the settlement of the existing controversy rests without either the operators or their employees. Mr. Lewis and his official editor have repeatedly laid stress on what might be called "the process of attrition" as the force that will ultimately break the deadlock which now exists; this was the method employed on Nov. 1, 1919. It failed then and it will fail now. To repeat, the country is saturated with fuel, and with nearly every union mine entirely stripped for the first time in years coal is a drug on the market and the 600,000 tons held in cars on mine tracks is quite unsalable. The large amount of coal in storage is not held by the operators for higher prices, as stated by Mr. Lewis and Editor Searles, but was bought at or below cost and is now far beyond the speculative seller. Mr. Lewis sought, some weeks past, an alliance with the unions representing the 1,600,000 men engaged in railroad service, the express purpose given being that of furthering the common interest of both classes of labor. Mr. Lewis and the writer are both advocates of the theory of collective bargaining, but differ in the determination of the territory that should be covered by the bargain. The writer advocates bargaining with the men serving the industry within the state or district wherein the mine is located. Mr. Lewis has more Napoleonic ideas of empire, he proposes that an Illinois operator bargain with all the miners on the North American continent, under rules originally "dictated but not signed" in Europe, the trade so made to carry the approval of all the railroad employees in the United States. Like that other historical character who once started a fight, he is given to taking in too much territory. The existing strike will be settled ultimately because of its effect on the transportation necessities of the country. In 1921, the railroad tonnage was 75 per cent. of that of 1920. For 18 months the transportation machine, with a subnormal supply of cars and locomotives, and an abnormal accumulation of deferred maintenance of equipment, road bed and buildings has rendered all the service the country asked for. The past few weeks point conclusively to a turn in the tide. Until the coal strike occurred, unemployment was decreasing; the steel mills, furnaces and factories have quickened into life, building is being resumed and the railroads have already purchased 70,000 cars against 28,358 ordered in 1921. May and June will pass without coal panic; with July will come the start of the great Western States grain movement; the Northwest will then begin to think of its dock coal movement and of the winter that settles down early in the northern tier of states; New England will want coal from all its usual sources of supply and when this time comes the ghost of a transportation shortage will beckon with an accusing finger. Railroad executives and the Interstate Commerce Commission have the transportation-demand curve for many years before them; it begins to climb in July. The curves showing revenue freight-car loadings for 1920–1921 and the first 11 weeks of 1922, Fig. 4, suggest the motivation that will determine the close of the coal strike. Few of us fully sense the insolubility of the relation that exists between the coal industry and the railroads. Above and beyond any other commodity, coal and its product, coke, make demands on the carriers. The chart, Fig. 5, shows the relation that these items bear to all other freight originating on our railroads. It will be observed that our manufacturers and merchandise which includes steel total less than 45 per cent. and all the products of agriculture total but 30 per cent. of the weight of the nation's coal and coke. It is Coal that is king, regardless of his past and present maladversions.

### How Permanently to Cure the Coal Cancer

The coal industry has been shown with lucidity as occupying a position vital to our whole industrial and economic structure; withal it is cancerous and the disease must be cured. The industry is not the private property of the owner and the mine workers, its foundation rests on a natural resource necessary to the whole people. The invested capital, directed by managerial skill, the mine labor, skilled and unskilled, the transportation companies, and most of all the public are dependent on the successful conduct of the industry. Operators and more recently union heads agree that the industry is overdeveloped. The mine workers, however, demand a unit wage sufficient to keep every man who can gain a foothold in the industry, whether or not the public requires his service and without regard to the wages due to capital. They further propose to reduce the potential weekly work period 37.5 per cent. by cutting the working time from 48 to 30 hours; they offer no plan, however, that will prevent the further development of mines that would undoubtedly follow. In substance, they ask that the equivalent of a second mortgage be put on the industry and the public who support it, for the temporary benefit of that six-tenths of one per cent. of the nation that pays dues into the mine-workers' organization. The consumers of coal are becoming tired of having their coal bins taken over and made the scene of recurring labor brawls, and as coal labor affairs are now conducted there is no assurance that any settlement that may be made of the existing deadlock will prove permanent; the country

Digitized by Google

may find itself in the midst of another coal strike on Nov. 1 next. Wholesome constructive coöperation on the part of those concerned will solve the problem. We do not wish to see the blighting hand of government ownership closed over the industry, stifling individuality and initiative, and wage commissions deluged with fragmentary and partisan statistics do not offer a good foundation for industrial peace. As stated by Mr. Hoover, quantitative thought and the exclusion of politics will furnish the solution. To the members of the Institute and the coal-consuming public, the following specific suggestions are offered:

1. The enforced incorporation of all labor organizations with provision that such be subject to all of the laws, rules and regulations that govern corporate or partnership holdings of capital, including the payment of federal income and excess-profits taxes.

2. The reformation of the United Mine Workers Organization, including the elimination of the check-off, with such revision of policy as will insure a better recognition of the relation the industry bears to our national economic life and a decent regard for public opinion; the organization to transform its present policy of resistance to greater individual productivity into one of productivity, including the giving of proper encouragement to the installation of labor-saving machinery.

3. Full recognition on the part of the employer that the mine worker is entitled to that fair living wage consistent with the American standard of living, regardless of whether he mines coal north or south of the Ohio and Potomac Rivers; the employee recognizing with equal force that to earn he must produce.

4. The enactment of legislation that will insure a full finding of facts concerning the industry.

5. From the facts so secured, the Secretary of Commerce should publish promptly, monthly and annually, the essentials that concern the public, including mine labor.

6. From the evidence so secured he should keep the Interstate Commerce Commission informed as to the ability of the then existing mine development to serve the full needs of the nation with that required for export and bunkerage.

7. The transportation act should be so amended as to require every railroad desirous of rendering transportation service to a coal mine to secure from the Interstate Commerce Commission a certificate of convenience and necessity before entering or serving same.

8. With a deflation of mining cost and a resumption of industrial activity, the industry would in three years overtake its present over expansion and gradually and without violence sufficient men would be withdrawn to give those remaining from 275 to 308 working days per year, more particularily if a campaign of education and encouragement of the public was directed toward an effort to eliminate seasonal demand.

## The Coal Consumer and His Strike

By J. D. A. Morrow*

THE above title seems to indicate a discussion of the present coal strike. The National Coal Association does not deal with labor matters or wage controversies. I shall adhere to that limitation and shall not discuss the policies or issues in the present strike. It serves here merely as an illustration.

The present coal strike is not John L. Lewis' strike nor the operators' strike, but is the coal consumers' strike. He is the man responsible for it; and this statement is made neither in praise nor blame. For a year the coal consumer has been making it painfully plain that he will have lower-cost coal. He has been readjusting the basic economics of his business and of his household. Among the items he early marked with red ink for reduction was the cost of his coal. Operators of certain non-union coal mines who can readily understand a fact as emphatically put as the coal consumer put the above-mentioned determination decided many months ago that it was good business to pay some heed and act accordingly. They did so. The coal consumer increased his business with them. Their employees, though on a lower wage scale, had more work to do and increased their weekly and monthly earnings.

The coal consumer withdrew more and more of his business from union mines where the production cost under the wage scale, and hence the selling price was above that of the adjacent non-union mines after they had readjusted their wages. The union operator could not lower his wage scale and the coal consumer gave him less and less business. His men had less work and smaller earnings than miners in adjoining non-union operations. The New England coal consumer is typical. He normally takes about half his bituminous coal from union and half from non-union mines. For months prior to April 1, however, he was taking twice as much from non-union mines as from union fields.

The coal consumer has the undoubted right to buy his coal where he can buy it most economically. The placing of his order determined whether union miners or non-union miners would dig his coal and receive a wage therefor. His choice closed many mines long before April 1, 1922, albeit the operator tore his hair in an effort to operate and the miners proclaimed their willingness to mine—at the union wage scale. The consumer had struck these mines. Walter McKinney, out at Columbus, tells me that the coal consumer struck 169 mines in southern Ohio for the whole year of 1921. Union operators are convinced that the consumer will continue his strike indefinitely unless they readjust their production cost, and therefore their wage scales, more or less in conformity with his ideas. More, they sympathize with the consumer and think him right. The United Mine Workers do not sympathize with him and think him wrong.

*Vice-president, National Coal Association, Washington, D. C.

Digitized by Google

Some politicians and some newspaper writers proclaim the present controversy as a strike of the miner against the operator. Dead wrong; it is a strike of the miner against the consumer, or vice versa, as you please. Some politicians may think it good politics to back the United Mine Workers because they have more votes than the operators. Dead wrong again; the coal consumer has far more votes than either the miners or the operators, or both combined, and it behooves all and sundry who love political preferment to remember that after all this is the coal consumer's strike. It may be that he is even proud of his strike and might bite the leg off anybody who tried to take it away from him.

Now for the moral. When we talk of stabilizing the bituminous coal industry, perhaps it would clarify our thinking if we would scratch out the words "coal industry," write in "coal consumer" and read it over again thus, "stabilize the coal consumer." We would then get a more accurate measure of the real problems involved in this much talked of stabilization. It is a very popular idea just now in Washington and elsewhere. Civic leaders, statesmen and lesser lights are devoting themselves to "stabilizing the bituminous coal industry" so that the mines will run more steadily, there will be less overdevelopment, less unemployment, less intermittency of work. There are not a few who think this a task for government. Before any such verdict is signed, sealed and handed in it might be well to consider the coal consumer, who has no reverence for the miners' union and may have no more for "stabilizers."

As matters stand now, said coal consumer can buy his coal anywhere he wishes at any time. He can even go and open his own mine and his own coal land. When we strip the current stabilization talk of its umbrageous decorations, most of it comes right down to a denial of these present rights of the consumer. If overdevelopment is to be checked, the opening of new mines must be controlled, and the unrestricted right of the coal consumer to open up his own coal for his own consumption must be denied. That will mark a fundamental change in all our ideas of private property since before the days of Alfred the Great. If irregularity and intermittency of operation are to be cured, the coal consumer's freedom to obtain his coal when and as he wants it must also be restricted.

Even so, this may all be well worth while and to the consumer's interest. Nevertheless, whoever urges such a program may well stop and ask himself the question "How will the consumer take to this proposal?" The United Mine Workers suggest stabilizing employment by a six-hour day and five-day week. The coal consumer will settle that proposal once and for all before he finishes his strike. He may be equally decisive in his action toward some of these stabilization proposals.

This is not written in opposition to conservation or stabilization, nor in depreciation of the need of a sounder business basis for the bituminous coal industry, of a surer return for capital and of better employment conditions for labor. Everyone connected with the industry understands the need for betterment in these respects and must hold himself in readiness to go far to bring them about. The coal consumer and his present strike serve to remind us, however, that in this practical world we must keep the gentleman in mind when we talk of conserving our coal measures and of stabilizing our coal industry. The big job is to make these things work with the coal consumer.

---

## Coal and Public Utilities

By W. S. Barstow*

THERE is no business in which the public is so vitally interested as that having to do with the mining and distribution of coal. While it is true that the operation of this industry at first thought appeals more to the individual in private life, yet it is soon realized that it is the very foundation of industrial existence. That the mining and distribution of coal has been permitted to function along lines of great economical waste, without exciting more than an occasional interest, is, therefore, the more surprising. An industry demanding the highest ability in management, as well as honest efforts on the part of labor, has gradually departed from all principles of commercial efficiency and is at this time seriously impeding the recovery of general business.

The industry having to do with the generation and distribution of electrical energy has been designated as a "public utility," and yet coal mining, which is the foundation of that industry, has not yet been included in this class. For many years the operations of public-utility companies have been regulated by state commissions, which were created as a protection both to the investor, in his investment, and the public, in its service. The largest one item in the expense of a public-utility company is coal; and on this expense must be based the charge to the public, as well as the return to the investor. When we realize that the mining and distribution of coal is conducted along wasteful lines, and is in the hands of those who seem to be free of all obligations to the public in stabilizing this industry, we can see how vitally every individual should be interested, through public utilities, in the coal situation.

In an endeavor to control to a degree the one large item of expense, many a public-utility company purchased a coal property, and then, more than ever, it was brought face to face with the coal-mining situation as it actually existed, and realized that in effect its functioning was worse than that of all other industries. If a public-utility company is to continue to give efficient service, at reasonable cost, the coal industry must develop along efficient lines.

# Some Issues in the Coal Wage Controversy

By J. G. PUTERBAUGH
President, The McAlester Fuel Company, McAlester, Okla.

MARCH 31, 1922, undoubtedly will be long remembered as the ending of an important epoch in the coal-mining industry. On that date, contracts fixing the wages and terms of employment at all anthracite mines and at approximately 60 per cent. of the bituminous mines of the country expired.

For the past two years, the consuming public has been complaining bitterly against continued high cost of coal. Coal operators employing union labor have felt obligated to carry out contracts entered into under the direction of the Bituminous Wage Commission appointed by President Wilson, and in order to do this, they have sacrificed millions of tons of business to non-union mines, and millions of dollars in wages that would have been distributed throughout unionized districts have been diverted to the non-union miners, many of whom never obtained the peak wages granted by the Bituminous Commission and others of whom accepted reductions early in 1921.

Heretofore, wage contracts have overlapped as to expiration dates in different districts and renewals have had to take into consideration the competitive balance; the present situation is unique in that practically every contract in the country expired on March 31, and the questions now confronting those responsible for the operation of the coal mines of the country are:

1. Shall the operators that have heretofore employed union labor endeavor to continue contractual relations with United Mine Workers of America?
2. Shall they undertake to operate their mines with non-union labor?
3. Shall they encourage and endeavor to work out some plan of regulation or arbitration by a Government commission such as President Roosevelt appointed to settle the anthracite strike in 1902?
4. Shall the country give consideration to the demand of the miners that the coal-mining industry be "nationalized?"

Operators that have endeavored to operate their properties with union labor are emphatic and practically unanimous in stating that they cannot and will not continue to be responsible for the management of their properties without a larger measure of authority and control than they have been able to exercise over union labor during the past several years.

Prior to 1900, the coal miner regarded himself as the slave of the operator. Gradually, since 1910, he has become the slave of the bosses of his union. He has very little to say as to the terms and conditions of his employment, as to when he will work or strike or as to the percentage of his total earnings that the union officials shall "check off" and require the operator to deduct from the wages of the "rank and file."

The employer is the natural leader and should be the "Big Boss" of those he employs. He should command their respect and their loyalty, and his prosperity should mean their prosperity. In the battle of business, one operator and his employees should be pitted against a competitive operator and his employees. Operators and men of one district should compete with operators and men of another district in their efforts to serve the public best, and profit in proportion to the success of their joint efforts.

The union idea completely abolishes the idea of loyalty and coöperation between employer and employee. Our illiterate miners, fully two-thirds of whom are foreigners and a great majority of whom are unable to read the English language, are constantly taught that their employer is their natural enemy, that he has no interest in their welfare and that he is seeking to get from them the most in service for the minimum return.

## Opposition Crystallized in Minds of Employees

Where substantial concessions have been made to labor, officials of the union have, for their political aggrandizement, taken full credit for having "forced" the advances; and in these and in many other ways, the minds of ignorant laborers and the minds of their wives and children have been crystallized into a state of prejudice, antagonism and envy against their employers, who are supposed to be piling up enormous wealth which does not belong to them. It is obvious that such a relationship does not work for efficiency and that the industry and the public must pay heavily for the continuance of such an unhealthy situation. As a result of increasing suspicion of employer by unionized employees, the employers of union labor have despaired of educating their men to a knowledge of the real facts and, in fact, have abandoned the field entirely to the officials of the union, the organizer and the socialistic press.

The soil, therefore, is in no condition to accomplish a friendly, coöperative understanding. It is far

Digitized by Google

from the mind of labor to realize or concede that a comparatively trifling percentage of the dollar the operator obtains for his product remains in his hands as profit. Neither do the laborers realize that, in a great majority of cases, the portion that does remain as profit is re-invested for the improvement and betterment of the mines which afford the opportunity to make a living.

Many who concede the right of labor to organize do not realize the tyranny of the enforcement of the closed shop. Thousands of miners in union districts, many of whom own their own homes, would be glad to be relieved of the tyrannical domination of union bosses and officials and of the deduction of a large portion of their wages as union dues. They are good, law-abiding citizens, and have no sympathy with or tolerance of the numerous petty strikes that are called for the personal aggrandizement of union politicians, but in union districts, the non-union employee who seeks employment at mines must be notified by the operator that his application cannot be considered until he has taken the oath of allegiance to the union, paid his initiation fee and obligated himself to obey its mandates.

### Union Torn by Internal Dissension

The union today is torn and seething with internal political strife, and the interests of the rank and file and the interests of employers are in every way subordinated and made secondary to the interests of the powerful leaders of the organization; and, as a result, operators, miners and the public alike are paying the penalty. The upward trend of wages since 1900, the credit for all of which has been claimed by the "organization," has enabled the union to prosper, both numerically and financially, but even the rank and file today realize that the organization has overplayed its hand and that this is going to make the problem of readjustment and liquidation doubly difficult.

The history of labor organizations is that their machinery does not lend itself to successful retreats and that the leader who accepts defeat is repudiated by his former followers, and those who have sown the wind to obtain preferment generally reap the whirlwind. The real controversies within the ranks of the union have little to do with the welfare of the rank and file, and no concern for the welfare of the industry and the public.

Obviously, such a condition is deplorable, and its continuance intolerable and entirely un-American, and it is clearly against the best interests of the American public that it should be tolerated or continued; those responsible for the coal-mining industry of the country will be derelict in the performance of their public duty if they do not insist on a radical and complete reformation.

Some operators in each district believe that a uniform and standard schedule of wages is desirable, and they have been encouraged by this idea to try to continue collective bargaining and the closed shop, but the great majority of union operators, if asked why they tolerate the continuance of such an unhealthy situation and why they do not go open shop, will frankly state that they hesitate to do so in the fear that their properties will be dynamited. Suits against the union for the value of properties destroyed in this manner have been brought and are now pending for final decision before the Supreme Court of the United States, and the public will doubtless soon know whether or not the United Mine Workers of America as an organization can be held financially responsible for the acts of its members.

Undoubtedly, many of the miners now classed as union men would welcome the opportunity to work under non-union conditions, if assured of protection and of not being again forced to go back into the union as "scabs."

As 40 per cent. of bituminous coal of the country is being produced by non-union labor, that has accepted readjustment of war wages, and as coal produced by this non-union labor has made heavy inroads, since the beginning of 1921, on the trade territory of union mines, and as there is ample producing capacity in these non-union districts to supply the country's needs for many months to come, even though the union operator is willing to bear the indignities of the system heretofore in effect, he cannot pay anything like the wages demanded by the union and compete with non-union mines. The wage schedules and market prices fixed by non-union mines, therefore, mark the key to the coming wage adjustment. Union operators not only will be destroying the value of their own properties and putting themselves out of business, but will be throwing out of employment union miners if they compromise or settle on a wage that will deliver the business to the non-union districts which are already the strongest and most powerful in the country.

### Labor Subject to Supply and Demand

This hard fact brings us to the realization that, after all is said to the contrary, labor is a commodity and is subject to the law of supply and demand. Mr. Gompers and other leaders of labor refuse to admit this truth, and are contending for the maintenance of certain human standards and certain "minimum" wages, without relation to the value of the service or what the public is willing to pay for it. A union carpenter or brick-mason will not buy union-mined coal if he can buy wood, fuel oil or natural gas more cheaply. Hundreds of members of the farmer's union throughout the West, during the past winter, have positively refused to pay the price of coal, and have burned the surplus corn. Union railroad men in Memphis, Tenn., or Chicago, Ill., will buy non-union coal from West Virginia or Alabama if that coal is obtainable at a lower price than union coal from Ohio or Illinois. The

Digitized by Google

operator and the property he owns is only the agency through which the miner sells his labor to the public in the form of coal. Therefore, is it not clear that, if the finished product must compete with the product of non-union districts, the real competitors are the miners of the two districts; and is it not apparent that, if union men themselves will not pay more for union products, the miners of union districts must meet the competition of non-union labor or abandon the industry?

Clearly, where the situation is so nearly balanced as in this country, the gage of the wage the union bituminous operator can pay is that accepted by non-union labor. Therefore, it would seem clear that either union labor must eliminate itself as a factor in the industry or become reconciled to the meeting of competition, just as employers must do in the marketing of their product. The officials of the United Mine Workers of America state that they do not propose to accept wages being paid to non-union labor as a standard. They steadfastly refuse to recognize the inexorable operation of the law of supply and demand, which has operated from the beginning of time and was not enacted by coal operators or by any human government, and therefore must be sound. We must concede that union leaders, during the past several years, have, by virtue of their control of mine labor, accomplished many seemingly impossible and illogical things, but whatever mistakes may be made by operators or Government in the settlement of this great question, it is obvious that the great law of supply and demand will not exempt labor from compliance with its operations, and clearly, much confusion and much destitution and strife and resultant human misery could be avoided if workmen could be told and made to understand the truth.

### Question of a Living Wage

One of the strongest and most plausible contentions of labor in the present controversy is that, even at the existing wages, the annual earnings of union miners during 1921 were sufficiently great in only a few districts to equal more than a fair living wage. In order to clearly consider this contention, we must not forget that the business depression which became most acute during 1921 was world-wide and that it was not to be expected that during such unprecedented periods as the world was passing through, and while thousands abroad were starving for lack of a few grains of corn, the people of this favored country would entirely escape their share of the punishments of war.

The miners' union, the railroad brotherhoods and many other organized groups are seeking to use the tragedy of a world war as a stepping-stone to a position of permanent ease and luxury which they have not earned by honest toil and service to humanity. They are using the power of their organization to wrest from a weakened world unfair advantages. By contending for a high paper wage, instead of conceding equitable readjustments that would materialize into greater, rather than less, annual earnings, they not only are blindly punishing themselves, but every consumer of fuel, and they are also spragging the wheels of returning prosperity.

The ignorant coal miner is struggling in the balance between what seems to be a logical and sensible course of procedure and the alluring theories, hopes and promises of an illogical and, in many instances, an insincere leadership.

Coal operators, railroad managements and the public should coöperate to equalize demand for coal throughout the different seasons of the year. There is no question that in districts where seasonal fluctuations are great they should be overcome by graduated mine prices and graduated freight rates. It might be further desirable to make seasonal fluctuations in wages. Except in war times, consumers can be encouraged to buy coal far in advance of requirements only when there is a mometary inducement for so doing. Transportation is such an important factor in the marketing of coal that the Interstate Commerce Commission should coöperate in the solution of this problem.

### Public a Controlling Factor

It is clear that there can be no return to normal industrial activity and coal consumption until the public is satisfied that the cost and selling price of coal, transportation, labor and building materials has declined to a firm and reasonable basis; and there is a feeling that these items are more likely to advance than to go lower. The country is standing still waiting for the coal industry and the transportation industry to get back to earth and to take pot-luck with the farmer and the many other groups that have had the courage and the foresight to take their "medicine," unpleasant though it was, and which, by virtue of their action, are now rapidly convalescing.

Apparently, it is the hope and belief of the miners that within a few short weeks the Government will again intervene and take upon itself the responsibility of a settlement, but in view of the magnitude, complexity and infinite detail involved in mine wage contracts, it is scarcely to be hoped that the kind of Government commissions that have functioned in connection with this problem during the past several years could or would bring about a settlement that would be equitable or in the interest of the public. No Government commission can annul or mitigate the keen and growing competition of non-union coal produced by non-union miners who are already accepting much lower wages than many of the union groups are offering to pay.

It is imperative that the coal miner reform his viewpoint and that, in return for the wages he receives, he undertake to render a full day of honest service; in other words, that he work for and not against the employer who gives him work and finances his payroll. The miner is sadly and viciously misled as to the

Digitized by Google

attitude of the employer toward the employee and his incorrigible attitude and consequent lack of coöperation is easily increasing by 20 per cent. the cost of union-mined coal as waste and without anything like a countervailing benefit to labor. The union miner is, or should be, more interested in the correct economic solution of this controversy than is any other interest, as, should he gain what his leaders are contending for, it would mean his own complete undoing.

In the interest of the public, their employees and themselves, the coal operators of the country, who know the facts and the real issues involved, should at any cost to themselves individually hold out for not only a proper and just readjustment of wages but for such control of their properties and employees as will enable them to operate efficiently.

## The Coal Miners' Demands and the Way to a Solution

By William Hutton Blauvelt*

THE present coal strike for the first time includes both the anthracite and bituminous fields, although the two industries have little in common except that their dissimilar products are fuels necessary to our national life.

In the bituminous fields, the present strike is the outcome of the demand by the United Mine Workers for higher wages. Claims that the operators in the central competitive field have broken faith by refusing to meet the union is a mere technicality. The demand for higher wages has aroused little public sympathy because the present wage rates are already far in excess of those now paid in other occupations calling for a similar degree of skill. The operator demands that lower rates of wages be established in order that coal may be delivered at lower prices to the consumers. Neither side of the controversy has touched the real problem, which lies far deeper. It is, undoubtedly, the fact that the cost of coal to the consumer and the cost of mining coal are too high. It is also true in very many cases that the miner is not receiving sufficient wages to assure him a reasonable living; but any agreement which may be reached as to wage rates will be only a temporary adjustment and the problem of the coal industry will still demand an economic solution.

The demand of the mine worker for a six-hour day and a five-day week meets no public response, especially in the minds of those who are working a nine or ten-hour day, five and one-half or six days a week. If the miner could be reasonably assured that in times of average prosperity he could have the same number of hours work per day and days per year as in other industries employing a similar class of labor, public opinion would soon settle his rate of wages in line with other industries. The problem of the bituminous coal industry in America is its stabilization in line with other industries producing commodities required for the public good; and since the coal industry is so basic to all industry, the need for its stabilization is correspondingly great. The solution of this vital problem must be economic, not political. Natural laws must be recognized, not disregarded. A situation must be established, which, acting in harmony with natural law, will produce the desired results.

At present the capacity of the bituminous mines of this country is about 40 per cent. above the requirements of an active demand, and more than 150,000 miners are employed in excess of efficient requirements. Many mines are and can be operated only during times of high prices, and during these times they take the cream of the business, leaving to the regular operators the long-term contracts at lower prices.

The naturally seasonal conditions of the coal industry add to the difficulties of the problem, but the Lake Superior iron-mining operators have stabilized their naturally seasonal work in large measure and possibly their experience may suggest something to the coal operator.

Unfortunately, the public is interested in the problems of the coal-mining industry only when prices are high. Before the war, it was said that in the state of Illinois the majority of the coal operators would be found to be insolvent if they were compelled to balance their books. At that time the price of coal was very low and probably only the best equipped mines were operated at a profit. The consumer was entirely satisfied to obtain his coal at prices that in many cases were below cost and there was no public demand for a solution of the conditions in the industry, although such a time would have been far better than the present for the working out of a plan for stabilizing the industry.

Any solution of the problems of the coal industry must be fair to all, including both regular operators, who have invested large sums in the development and equipment of their mining properties, and those who operate only during periods of high prices; but it is clear that the "snowbirds" and wagon-mine operators add seriously to the difficulties of the problem. The public is convinced that national ownership of the mines is not the solution, but that some form of organization for coöperative effort, with proper governmental supervision, would cure many of the present evils, if the right plan can be found. When public interest requires it, coöperative effort can be legalized for the coal industry, as it has for the farmers and for the export trade.

Railroad transportation and car supply are so intimately connected with the coal-mining industry that it is possible that we may find there an important aid in stabilizing the production of coal. Possibly a plan could be worked out that would give some form

*Semet Solvay Co., Syracuse, N. Y.

Digitized by Google

of preferred car supply to the regular operators, based on their previous requirements over a period of months. Although this might work hardship on some, the greatest good to the greatest number must finally rule, and the public interest demands a permanent solution of the situation and an elimination of the highly uneconomic conditions now ruling throughout the industry.

The public has confidence in Mr. Hoover and the Department of Commerce of which he is head. I believe that a study of the situation, initiated by Mr. Hoover, on the lines indicated above, and carried out by men who will forget partisan politics and seek only the true economic solution, would bring an answer acceptable to the public and satisfactory to the great majority of operators and miners. No national problem is more vital to our industrial success today, or more in the minds of the public and those engaged in the industry, whether as operators or miners.

## Clouding the Coal Labor Situation

By Carl Scholz*

EVEN to the casual observer, it is obvious that the present coal strike is the result of several years' propaganda on the part of the miners' leaders, who have used every effort to monopolize the industry, and it is remarkable to what extent they have been encouraged by a part of the press and a number of politicians.

Although nationalization of the mines has long been one of the hopes of the leaders, not until now have they been bold enough to announce this policy publicly. This demand is so absurd that even such politicians as have favored the miners' side in the past have taken no interest, and perhaps have not given this demand any more serious consideration than the request for a six-hour day and five-day week, which the editor of the *Mine Workers Journal*, in a recent article to the *Saturday Evening Post*, says was not made seriously. That is just about the way in which the demand for the check-off was made 20 years ago; nothing serious, just a little help in collecting the dues, is the manner in which it was put to the operators of Ohio, who first collected the check-off. When the proposition was presented to the operators of Illinois, it was expressed in a more positive manner, then it became and has remained the chief bone of contention during the last 20 years in the other 15 coal-producing states where it has been in effect since that time. When we stop to consider that a part of the $20,000,000 collected annually has been used to fight some of the state governments and to cause an enormous expense to the Federal Government, we look upon it as a really serious situation, and one that may well engage the attention of the Federal judges who are being advised of the menace which this check-off is to the country. For illustration, the Logan march cost the Federal Government $1,000,000 in 1921 by bringing troops to West Virginia. No mention has been made of the cost of the various commissions and committees and legislative investigations which have been instigated by the miners' leaders, without any foundation whatever except self aggrandizement of the officials and a possible increase of the check-off as a means of revenue and fighting fund.

Just as the check-off became a settled fact as a result of constant effort, so it has been the hope that nationalization and reduced hours will come about.

During the war the miners' president, pleading for an increase in the miners' wages, on account of the higher cost of living, said that unless these increases were made the miners would desert the fields and engage in other occupations. At the same time, every effort was maintained throughout the war period to reduce production per man employed by prohibiting any man from doing more than one class of work, even if it required only a fraction of a day to do it, and such inconsistencies have been conducted by the miners' leaders to this very day. In the organized fields, the percentage of day laborers compared with loaders and machinists has been constantly increasing, and the cost of production has increased on this account, even more than by direct changes in wage rates.

It is not wholly impossible that the underlying reason has been the desire to increase the income of the national organization from the check-off, because in the bituminous field every additional man employed means something like $20 per year to the national organization. In the anthracite field, where the check-off has heretofore been limited to $1 per month, the main fight is made for the unlimited check-off. The coal consumer pays not only the cost of the check-off in his coal bill but also the damage caused by it, which is perhaps ten times greater. It is generally conceded that the check-off in the bituminous field is about 5 cents per ton, and the cost of production by restriction of day labor is estimated to range from 20 to 60 cents per ton. These figures are authentic and can easily be verified.

Now the miners' leaders ask for a reduction in the hours worked per week at the top war-wage rates, in order to furnish employment to a greater number, claiming that the present wage is necessary to maintain the large number of men working in and around the mines.

What would the farmer reply if his hands should say that they wanted to work only five short days per week, so that all could be employed, but they would have to get their board and full pay? If this theory is correct and work in the mines is made so attractive, by the time the next contract period comes around it would be quite feasible for the miners to ask for a three-hour day and four days per week, and ultimately they would have to be maintained without doing any

* Vice-president and General Manager, Raleigh-Wyoming Coal Co., Charleston, W. Va.

Digitized by Google

work at all, merely for the pleasure of visiting the mines. This is wholly contrary to the principals of competition and the inexorable law of supply and demand.

Those who do not deal with the miners and their representatives do not understand the methods resorted to, and may be interested in a few illustrations. When the illegal strike in the fall of 1919 was in effect, Mr. Lewis promised President Wilson to call off the strike and did so, but Mr. Wilson had failed to exact a promise that the men would return to work, and the miners remained idle. Now, in any other industry, when a strike is called off it means return to work, but not so with the miners. General Banholtz had the same experience when he investigated the Logan march: the miners' leaders, who had ordered the men to march to Logan, promised the General that they would recall them, but the men did not return, for reasons that were well known to the coal operators, and General Banholtz was compelled to go back and take several thousand soldiers before the miners returned to their homes. In the bituminous commission award, the miners agreed not to obstruct the introduction of labor-saving devices, but this agreement has been violated a number of times.

The officials of the companies who sit on the grievance boards can furnish hundreds of examples where the miners' officials used their wits to retard production and increase the cost, and it may be said that they are usually well informed and by no means backward in threatening strikes to gain their points. In this country, where the greatest opportunity exists for cheap fuel, and lower fuel costs mean reduced freight rates, we should have increased production by increasing the demand from industries; there should be prosperity in every hamlet instead of cries of poverty and subscriptions for the starving; but with wages increased three fold within the last 10 years and a reduction of 50 per cent. in the output per employee, we find ourselves confronted with conditions that engage the attention of Congress, when if such a move were made by any other class of labor it would be dismissed without a moment's consideration.

If left to the coal producers, the question of production will soon take care of itself. If the business is over-capitalized, the excess capital will be lost, and the loser will have no more claim for his losses than the miner should have for the wages which he does not earn.

In several foreign countries the syndicate plan has worked successfully, because it has eliminated a tremendous economic loss by keeping only enough men at work to produce the required tonnage and has afforded steady work for the men engaged in the industry, and has utilized the capital to the best advantage by keeping the mines constantly at work. It has also carried with it an obligation to work and has reduced strikes to a minimum, all of which results in reduced cost of production. Under the existing laws of the United States, such a syndicate plan is not feasible, but the results abroad have appealed favorably to investigators from this country, including the engineers of the Bureau of Mines and some members of the Federal Trades Commission, particularly Edward Hurley.

Through prolific, but unscrupulous, press agencies, the miner's story has been put before the public in a manner to cloud the main issues, because the regulation of production could not in any way be connected with the labor problem, as these are separate and distinct matters.

The greatest impetus which the miners' leaders received dates back to the signing of the Adamson bill, at which time the Gomperized White House dealt with a feeble hand with a situation that required practical knowledge rather than idealistic dreams.

---

## Fallacies of the Coal-strike Situation

By J. B. Warriner*

THE faults of the mine workers are due to lack of understanding of economic and industrial conditions, and of the natural laws that govern such conditions. The blame for this situation, if blame exists, and the remedy as well, are sociological problems, with which we are not here concerned.

It is a more serious fact, however, that the tendency of the mine workers, as of most other working men, is to follow the leadership of those whose comprehension of economic problems is of the same order as their own, rather than more conservative and thoughtful men; for this reason, their leaders as a rule do not pass down to followers, who watch with always a suspicious and sometimes a jealous eye, the facts they learn from better informed men during negotiations of wage scales and agreements. These conditions, unfortunately, are inherent in labor organizations. They will be with us, to some extent at least, as long as unions of employees exist; and such organizations are still a useful part of the social body, and will be in existence, though perhaps in modified form, for many years to come.

The only proper quarrel that we can have with employee organizations is over the fact that they have become too powerful and too involved in organization politics to function fairly and without menace to the public. The mine workers' organization, for instance, covers so many and such divergent fields that local matters in any one field, easy of settlement by themselves, are made the sport of quarrels between leaders and would be leaders, with too little reference to the intrinsic merits of the problems themselves. In time, these things may adjust themselves, but until they do so, the organization is not one to command confidence. This is the time for plain speaking, and

* General Manager, Lehigh Coal and Navigation Co., Lansford, Pa.

Digitized by Google

much as I am in sympathy with the principle of employee organizations, I cannot view their present trend without apprehension.

An equally serious difficulty in the present situation is lack of comprehension by the public of questions involved. This is not an unnatural condition. Coal mining is a complicated industry with innumerable phases and ramifications. Our newspapers publish confused and complicated facts and rumors from all the mining fields, giving equal weight to irresponsible propaganda and to the carefully considered and provable statements of spokesmen for the employers. The public, naturally, is unable to discriminate between facts and propaganda, or to apply known facts to the proper mining fields. Thus, even clearly marked and fundamental differences between the anthracite and bituminous situations are not always differentiated in the public mind. This is not strange, but it is regrettable. The American people are too apt to pass judgment on matters of which they are not fully informed, and the efforts of thinking men everywhere should be given to combatting this tendency.

At this time, it is true, the public seems to have a clearer appreciation of the issues involved than ever before, but its judgment is still swayed by certain widespread fallacies. The public believes, for instance, that the profits of coal mining are unreasonable; though numerous investigations have proved the fact that no great industry in the United States is operated on so small a margin of profit; many also believe that the operators of the coal mines are their natural enemies, though the fact is that the operators stand, and have always stood between the public and the exactions of labor unions, and have held the price of coal to reasonable figures at the risk of all the losses attendant upon industrial strife with their employees. The public at these times usually has given its support to the side of the labor unions, and therefore has reaped what it has sown, or has deserved that fate.

Another widespread fallacy is the belief that industrial strife between employers and employees in the coal industry has resulted in suffering to the public through shortage of coal and high prices. There is always the threat of a coal shortage when wage agreements expire and must be renewed by negotiation, but the fact is that the public has not actually suffered from a shortage of anthracite coal for at least 20 years, and, so far as I know, has never suffered from a shortage of bituminous coal. I cannot argue in detail the justness of anthracite coal prices, and can only reiterate what has been said so frequently by spokesmen for the anthracite operators, that the present prices of anthracite coal at the mines are due almost entirely to high labor cost, and that these prices will undoubtedly be deflated at this time in line with the general deflation, which the public has willed since the war in the price of practically all other commodities. Personally, I should be glad to see anthracite mine workers' wages remain where they are, if this were an economic possibility. The mine workers, however, are a part of the general public, which, aided by economic conditions, has forced prices down in all other lines, and they cannot avoid the workings of the same law, or consistently desire to do so.

My connection is with anthracite operations and, though I have kept informed of conditions in the bituminous fields, it is impossible for one not directly connected with those fields to grasp fully all the ramifications of the questions involved. Nor do I want to fall into the same fault for which I blame the American public, of passing judgment on complicated matters of which I do not have full and detailed information.

I agree with Mr. Hoover that the bituminous industry is overdeveloped, and that, from an economic point of view, it functions badly. I cannot agree, however, that so far this has been to the detriment of the public. The great overdevelopment of the bituminous fields has been an insurance against any shortage of this essential commodity at any time or place. It has also induced intense competition, with resultant low prices. Before the war three tons of bituminous coal could be mined by complicated processes underground, brought to the surface, loaded into railroad cars and sold at about the price of a medium-quality pair of shoes. In many cases these prices were less than the cost of production, and present prices are only moderately increased over the old. In the long run, however, it is not to the benefit of the country that such conditions should exist. Posterity eventually suffers when resources are wasted and industries are starved. I do not believe, however, that there is any remedy for the situation that can be applied from outside the industry itself. The bituminous operators, granted exemption from amateur interference, should be able shortly to solve their own problems.

## The Coal Problem in Wyoming

By P. J. Quealy*

THE instability and present condition of the coal business, I charge most positively to radicalism in union labor as the chief factor. I admit and believe that both skilled and common labor, while employed within the mines, are entitled to some better pay than like classes of labor employed outside.

In the great majority of work required in the production of coal in the mines, there is very little skill required that could not be acquired in a few days. The conditions of labor in the coal mines, as compared to other labor on the outside, are not unfavorable; and I speak from personal experience, having worked as a miner for nine years after I entered the mines as a boy until I became a foreman at 21 years of age. In fact, once a

*Vice-president and Manager, Kemmerer Coal Co., Kemmerer, Wyoming.

Digitized by Google

man is initiated in the mines, it is preferred to similar labor outside.

Therefore, the demand for shorter hours than eight, or double time, etc., is unreasonable. The present demand for wages, as required by the international union, in the mines, which is equal to more than double what similar labor is paid for outside of the mines in other industries, being $6.94 for common labor outside the mines and $7.50 and up inside the mines, is unreasonable. These rates should not be allowed, as they practically double the labor cost of coal production as compared to labor cost in other industries. The contract labor per ton is also relatively high.

The demands made by the unions at the last international convention at Indianapolis, for shorter hours and five days a week, etc., on account of the seasonal character of the occupation, are just as unreasonable as if applied to any other industries affected by seasonal demand, of which there are many; as the same class of labor is busy at other available occupations during the summer season when the surplus is not required at the mines. The principal reason why coal miners refuse to leave the mines and seek other employment when some mines are working only two or three days a week is that they earn so much more when they do work, per day, than the same class of labor is paid for at other available occupations.

Just as long as the present relatively higher rates are paid in and around the coal mines, union labor will insist that the rate of pay must not only be maintained but that it should be increased in order that the men may remain idle one-half the time and still earn sufficient to maintain a family for 365 days, which, if acceded to, must be distributed in increasing the cost of every commodity produced in any industry requiring steam power for its production, and in turn, the cost of living, of which we all complain so much.

I do not believe that prices or wages should be reduced to a pre-war level at the present time, if at all. Some changes have taken place in the world at large which we should recognize as a step forward and beneficial to all classes, requiring more money to maintain; this condition should be recognized and maintained up to the limit of our ability to maintain as a nation our industrial, social, financial, and political position in world relations. This condition cannot be accomplished successfully unless all classes alike, whether in the exchange of labor, the use of capital or political authority, work together under the advantages afforded us by our American institutions.

I believe the present policy of centralizing power by the international coal miners' union, requiring all outside districts to conform to wage and working conditions decided upon at a convention at Indianapolis in the Central Competitive Field where they are not represented, raises in the national coal industry the issue that was the cause of the American Revolution (taxation without representation); besides the loss of time by hundreds of our best miners and operators attending such conventions for weeks at a time, when the same results could be obtained in the several districts, where competitive production and conditions of labor are more uniform or the same. Wyoming, I have no doubt, would not be involved in the nation-wide strike if this condition were not in effect.

In proof of the statement that unreasonably high wages are not justified, and are of no economic advantage to the miner himself: In 1920–21 we were operating a lignite mine where, by reason of the natural advantages of a thick and pitching vein, 23 miners produced, when they worked, 600 to 650 tons per day; at the contract rate exacted by the union, a miner could earn and did earn as much as $20 per day, some more than that, some with an average of probably $13 to $15 a day. The mine worked only 151 days in 1921, while our other mines worked almost steadily. I could not induce the surplus men to accept employment in the mines that were working full time, because they could earn over $2600 a year by working two or three days a week at a lignite mine.

This coal was produced and sold to the public at practically one-half the price, and at less margin of profit than the average price of other coals. Had the labor cost been in proportion to the labor required for its production, it could have been sold much more cheaply, and the miners could have been employed 287 days at the other mines instead of 151 days at the lignite mine, and have earned a much greater sum, at a great advantage in production of coal which the markets required at that time. The miners, by this condition forced by the union, were encouraged to be idle at the expense of the public.

As to the stabilization of the coal industry, from a practical standpoint, I can now see but two possibilities that would, to some extent, relieve the situation of overproduction, namely: (1) To induce the union miners, or the men employed in the mines at the contract rates, to accept such prices per ton as would yield them a fair and satisfactory wage, applying reasonable industry and reasonable hours; (2) Since the leasing act of Government lands, a great many applications are being made and approved for new leases for the development of new mines, which will further increase overproduction and reduce the working time of the mines. This is within the power of the Government to regulate; before such leases are issued, a proper investigation should be held, or hearing, to determine whether the market where the proposed mine is to be opened requires the increased production contemplated by the new lease.

This suggestion does not apply to those already engaged in the business in territory adjoining public land; where the boundary has been reached, the lease should be extended to continue such operation, to prevent the destruction or the abandonment of capital assets and equipment.

# Why does the Coal Industry Need Stabilization?

By GEORGE S. RICE

Chief Mining Engineer, United States Bureau of Mines, Washington, D. C.

SINCE my earliest recollection, the coal business has been in a state of unrest. It has always been a matter of bewilderment to the serious thinking, the instability of this most important industry; second only to agriculture in its effect on the great development of this country, and even more important in certain aspects, because without fuel railroads could not run, agriculture could not get its products to market, nor would the great manufacturing enterprises have been possible. I will not attempt to discuss the present serious labor dispute or similar disagreements of the past, in the settlement of which more or less successful attempts have been made to equalize, temporarily at least, natural conditions through "joint agreement" as to prices paid labor; but will confine my views to the general underlying conditions of which the disputes are symptoms, and try to show how these must be remedied before there can be any hope of stabilizing conditions.

## Our Coal Resources

The United States possesses about half of the coal resources of the world, and unlike conditions in Europe and many other parts of the world, the mining conditions are remarkably good. The coal lies high in elevation so that, except in limited areas in the Rocky Mountains, there is no deep mining, in the sense that there is deep mining in Europe. This has made it easy to open mines, and where the coal outcrops at the surface, as it does in the great majority of the coal districts, it becomes comparatively inexpensive to open new mines. The result has been that whenever there has been a special demand for coal, following periods of unusual prosperity, or following suspensions of work, in one part of the country, many new mines have been opened.

## Bituminous Industry

The business promoter has aided in the rapid development of new mines by securing options on coal rights from the farmers followed by the organizing of new mining concerns with the incentive of large return from a comparatively small investment. It has been a matter of comment that those relatively few men who have attained great wealth in the coal industry have not become rich through the production of coal, but by the buying, development and sale of coal lands.

The greatest problem of overdevelopment of coal-mining capacity arises with bituminous coal, of which this country has such vastly greater reserves than of anthracite. Fifty years ago the production of coal in the United States was insignificant as compared with the established coal industries in Great Britain and Germany, but with the rapid expansion of the bituminous industry, mines have multiplied and the production has nearly doubled every 15 years. Between 1900 and 1916 inclusive, the last year of normal production, the average annual increase in production of bituminous coal was 18,000,000 tons (2000 lb.). The number of men employed in the bituminous production rose from 304,000 to 561,000, which was not in proportion to the production, the saving in man power being effected by the rapid increase in the use and effectiveness of mining machines. During this same period, the number of days that the mines produced coal varied from 195 to 234, or an average of 217 days. Mines owned by railroads and large industrial establishments are generally developed to supply only minimum fuel requirements of their respective owners, and therefore usually work 300 or more days per year. On the other hand, most mines supplying the general trades work fewer days per year than the average figures given above. If all the bituminous mines worked 300 days in the year, the potential production in 1916 would have been larger by 150,000,000 tons, or 30 per cent. more than was actually produced—503,000,000 tons; this was in a year when the mines averaged 230 working days.

## Storage of Coal not the Panacea

The storage of coal has been much discussed, and recommended as a remedy. It is unquestionably a benefit in equalizing production and in preventing local shortages of coal in the winter months, but it is not a remedy for the manifest overproductive capacity of the mines and their employees. Its effect is that of a flywheel of an engine, not of the engine itself.

Every year a certain number of mines are worked out or abandoned from other causes. It is difficult to get at these figures precisely, as only limited statistics are available. Without going into details as to the source, the writer, during the period mentioned, estimated that the average lifetime of the bituminous mine was about 20 years, which would mean that in the year 1916 a production capacity of about 25,000,000 tons was lost. Assuming, for practical purposes, that this figure is

Digitized by Google

roughly correct, an increase of the mining capacity is required of 25,000,000 tons for replacement, plus 18,000,000 tons, increase, in consumption rate, equal to 43,000,000 tons annually to take care of the constantly increasing bituminous consumption needs of the country.

We have already indicated that the estimated potential productive capacity of the mines, if they had worked 300 days in the year in 1916, was 150,000,000 tons in excess of that produced. If, therefore, no new mining capacity had been opened up following 1916, four years later the production capacity of the mines would have fallen below the normal increase in consumption of bituminous coal in the country.

It would not be wise or desirable to have no margin of capacity over consumption, so that even the restriction of new mining developments over a period of two or three years would bring about conditions where there would be comparatively steady work in the industry.

### Anthracite Situation

The situation in the anthracite districts of Pennsylvania is far more stable from an industrial standpoint, due to limited coal reserves. With these largely in the hands of strong mining companies, there is practically no opportunity for starting new enterprises in virgin districts, as in the case of bituminous coal. Accordingly, the annual increase of production has been relatively small. In the 10 years from 1907 to 1917, these years being selected as a normal decade of increasing production, the increased annual production was from 85,600,000 to 99,600,000 tons of 2000 lb., which is an average of but 1,400,000 increase for each year of that period. New mining developments therefore have produced little more tonnage than enough to replace the loss of production of abandoned and failing mines.

The annual increase of production, or even its maintenance, has been increasingly difficult despite the continued modernizing of mining equipment. This has resulted from the working out of the thicker coal beds, hence the necessity of mining thin and more impure beds, and the remining of old pillar workings. This, in turn, has necessitated the building and the operating of more elaborate cleaning plants for disposal of the impurity. Also, there has been an increasing quantity of water to be pumped from the mines as the extensive workings have fissured and caved, the ground thus admitting surface waters. In some instances the weight of the water elevated by pumping is over 10 times the weight of the coal hoisted. It must be admitted frankly that the peak of production of anthracite has been reached; it is possible that the production of 100,000,000 tons in 1917 represents the high mark, and hereafter there will be difficulty in again attaining this annual production even in years of prosperity. In fact, it is expected that in comparatively few years there will be a slow decline in production of anthracite.

The increasing difficulties of underground mining and cleaning necessitated such extensive mine power plants that over 10 per cent. of the production has to be used at the collieries in securing the shipped product. These increasing burdens are reflected in the increasing amount of labor and cost of supplies for production, without reference to the changes in the labor scale, hence it was inevitable that the selling price at the mine should increase, and the rate of increase must continue more rapidly than that of bituminous coal. Therefore, the anthracite industry does not reap the full benefit of the increasing consumption of the country, but, in fact, has had difficulty in holding markets which formerly it supplied exclusively. Anthracite has thus become a luxury. Nevertheless, in the period from 1907 to 1917 inclusive, the average number of days worked ranged from 200 to 285, or an unweighted average of 240 days as compared with 218 days for the bituminous mines. A matter of importance in favor of the stability of the anthracite industry arises through the relative uniformity of division of work which does not prevail in the bituminous industry; as between the bituminous mines owned by the railroads and large establishments to supply their fuel, and the bituminous mines supplying the general trade requirements which fluctuate widely in the different seasons. A factor which assists in the regularity of work at the anthracite mines is that anthracite may be stocked indefinitely without material degradation or danger of spontaneous firing.

### Further Consideration of Bituminous Mining

The foregoing discussion indicates that the greatest difficulties in stabilization arise in bituminous mining, in which there was a peak of production in 1918 of 579,000,000 tons and a drop to 407,000,000 tons in 1921, and under present conditions there seems to be no relief in sight, from too much mining capacity. Except for the period immediately following the war, when both the miners and owners profited greatly, the bituminous industry, statistics show, has had the lowest returns on capital invested and is the most unstabilized of the great industries of the country. Only exceptional bituminous mines supplying the general trade previous to the war paid reasonable returns over a period of years, and the record in many districts has been failure after failure.

Bituminous miners in most years up to 1917, and again in 1921, have suffered greatly in the shortage of work at different periods in the year. Miners and their families require food, clothing, and the necessities for 365 days in the year. If a man can get but half-time work, and a great proportion of the bituminous miners do not get more than this, he must receive at least double the minimum living daily wage to support himself and his family. The labor rates have been fixed on this basis so that tremendous inequalities are found between different groups of mines, and this in

Digitized by Google

itself constitutes a tax upon the consumer and calls for what seems like excessively high daily wages compared with other industries. It must be considered that mining is a peculiar occupation. The miner must be on hand to take the work when it offers, and moreover, it tends to unfit him for other kinds of work, and rarely are there other kinds of work available in the vicinity on the days when the mine in which he works is idle.

The mine owner suffers from the irregularity of production. Even a small surplus of coal on the market rapidly drives down the selling price to cost price, or even below it in the periods of poor work. Generally it is not physically possible to store considerable quantities at the mine, and further, the loss from the weathering and degradation of bituminous coal and cost of handling is prohibitive when the price of coal is low. Storing at the place of use is admirable, but with exceptions this practically can only be done by the consumer and local distributor. Idleness of mines is a serious expense which is not realized by the public, but overhead charges, including taxes and processes such as pumping and ventilation, have to go on regardless of whether the mine is working or not; also, slacking of the roof and continuous ground movement, calling for timbering, is a continuing expense. Who bears the cost of this? Ultimately it must be the consumer. Under pre-war conditions, mine operations in Europe worked practically every working day in the year, and generally coal was hoisted on two shifts instead of the one 8-hour shift universally used in the United States with consequent idleness of an expensive mining plant of more than one-half of the 24 hours, every day. Metal mines of the United States always are expected to work at least two shifts per day.

### Six-hour Days and Five-day Weeks

Miners, from time to time, have proposed a six-hour day and five days a week in order to spread the work, but expect to receive a proportionally larger wage in order to obtain the same monthly or yearly income. Such attempts are surely wrong from an economic standpoint, and with the inevitable increase of mines under present conditions in this country, the relief would be but temporary and the burden of added cost would have to be borne by the consumer. What is the remedy? The hope of the writer, which has been expressed from time to time during several years past, is temporary restriction in the opening of new bituminous mines, in districts already over-supplied with mines, in order to lessen the burden of this tremendous economic loss from periods of idleness and to keep down the cost of producing the coal.

It is difficult for even intelligent people who have not studied the matter to understand that a greater number of mines does not mean greater competition, and hence lower prices. It does have this effect for short periods in the year, but looking at it in a broad way, the results previously described must inevitably make an increased cost of coal.

The Government has a similar problem in the leasing of coal lands on the public domain. Under the Act of Feb. 25, 1920, the Secretary of the Interior may lease or give permits to mine tracts of coal land not exceeding 2560 acres in the public domain. Congress in making the provisions of this Act did not take cognizance of the possibility of more mines being opened than would be needed. At the present rate of issuance, at the time of writing this statement, 190 leases, licenses, and permits have been approved for issuance. The territory to be served by the mines from the Rocky Mountains to the Pacific consumes only 40,000,000 tons of coal per annum, and the existing mines do not have full-time work. If developments proceed as leases are granted, except those in extension of existing mines, the new developments will have a potential productivity annually of a number of million tons, thus dividing a business already, in normal times, oversupplied, causing hardship to those already in the business, to the miners, dependent upon the mines, and creating a burden upon the respective mining communities. One of the effects already indicated due to over competition will be the mining of only the best and thickest of the coal beds, and perhaps losing, for all time, many areas of thinner and somewhat more impure coal surrounded by the abandoned workings of the thicker areas.

### Governmental Permission for Trackage to New Mines

In this case, the remedy is comparatively simple, that the Government should not issue a lease in any district unless it is shown to be needed for additional production in that district. How can the restraint of opening up new mines be affected in the far greater privately owned coal areas of the country? The writer's proposal is that this should be done through some such governmental agency as the Interstate Commerce Commission, which would require that before railroad trackage or interstate rates should be given to new mines the prospective operator should demonstrate to the Interstate Commerce Commission that there was need for additional mining capacity in the district he proposed to serve.

At first this proposal may seem to be a severe hardship on the owner of coal lands, but when it is considered that it would not be permanent restraint, but in most cases would be only for a period of several years, as indicated previously, then the owner would be recompensed by the greater stability of the business when he entered into it. Moreover, the plan would be based on the theory that it would be for the good of the greater number of citizens. To some, the method may smack somewhat of paternalism, but on the other hand, the Government, states and municipalities exercise restraint without destroying iniative or private control as in connection with public utilities. Fuel, theoretically

Digitized by Google

at least, should be considered our greatest public utility. The plan is not altogether an untried one. Before the Sherman Act became a law, it was quite customary for certain railroads to discourage new developments on their lines already well served by coal mines. On such roads the work of the mines was more regular. On the other hand, mines on railroads that did not exercise such restraint were constantly in bankruptcy and the communities dependent on the mines suffered through the intermittent work. Again, during the war, the new mining developments were virtually under the control of the Fuel Administration and, despite the criticisms of the mine operators of some phases of that Administration, for the first time in the history of the bituminous industry, there was stabilization until the end of the war, and the operators had reasonable returns. It will be admitted that if the plan were carried out it would require very careful handling by the Interstate Commerce Commission to prevent injustice, but as it would be carried on probably through public hearings, and in effect court methods would be followed, it does not appear that it would be any more difficult a matter to settle than obtains in the determinations of important tariff rate changes between one part of the country and another.

In concluding, it is thought that, whatever may be the final settlement between the mine operators and miners, unless recognition is given to the need of a remedy for too many mines and too many miners, no settlement will bring about permanent stability in the industry. Attempts to equalize variations in natural conditions by fixing labor contract rates on the basis of the most difficult mining add to the cost of the consumer. The only way that low cost can be obtained is by keeping existing mines, and their employees steadily at work, not perhaps 100 per cent. of the possible working time but at least 85 or 90 per cent., in contrast with only 60 or 70 per cent., and in many districts less than 50 per cent.

The great development of this country has been founded on cheap coal and it is to the interest alike of owners and miners, as well as consumers, that the cost be kept low, with due regard to a decent scale of living for the miners and suitable returns to the owner for risking capital in a more or less hazardous business.

## The Coal Industry is Sick

By R. M. Atwater, Jr.*

THE trouble with the coal miners is part and parcel of the trouble with the coal business. The difficulty the public is having in getting a clear understanding of the rights and wrongs of the strike is due to the complication of many conditions bearing upon the situation which have passed beyond the control of the principals to the quarrel.

* Mining Engineer, New York City.

The coal-mining business, both anthracite and bituminous, has been built upon a foundation of unbusiness-like practices and expedients which, in many instances, were accepted as temporary and became permanent through extended usage.

The outstanding evils of the bituminous coal industry are, in my opinion:

1. Too many mines.
2. Too many miners.
3. Too much seasonal variation in consumption.

In the case of the hard coal mines:

1. Too many miners.
2. Too much seasonal variation.
3. Too much railway politics.

It is not difficult to find remedies for these troubles, the difficulty is to persuade the owners and workers to adopt the remedies. Legislation cannot solve the problem; nor can any overnight change bring about a solution.

The only suggestion that I will offer is that our Government confine its activities to asking the American Institute of Mining and Metallurgical Engineers to appoint a committee to advise the Government and, incidentally, to pay the committee properly for its work. The coal industry is very sick indeed, and it needs the care of specialists.

## Mine Strikers Accused of Undercutting Labor

A SPECIAL dispatch to the New York *Herald*, from Wilkes-Barre, on April 18, said that striking anthracite miners who were taking the places of men in other lines of endeavor were branded as "unfair workmen" by some of their own union leaders.

Alex. Campbell, member of the scale committee negotiating with the miners in New York, informed striking miners in the Pittston district that reports had reached him that strikers were taking jobs of laborers, cutting wages in some instances from 55 to 35 cents an hour.

"These men are unfair to organized labor," declared Campbell. "They are cutting the wages of other laboring men while clamoring for an increase in their own wages."

## A. R. E. A. Proceedings Wanted

THE Engineering Societies Library would like to have the Proceedings of the American Railway Engineering Association for 1918, 1919, and 1920. The Association cannot supply them. If any member of the Institute knows where these volumes can be obtained, he will confer a favor by writing to H. W. Craver, Director of the Library, 29 W. 39th St., New York, N. Y.

# Untenable Position of Union in Coal Strike*

By EDWIN LUDLOW

Consulting Engineer, New York, N. Y.

THERE has been so much misinformation sent out through the newspapers, and I find so few people who are really acquainted with the true facts in regard to the coal strike, that I feel it would be advantageous to present the facts as I have been able to gather them.

One of the great points that the miners are now making is the fact that the operators of the central competitive field, consisting of the states of Illinois, Indiana, Ohio and Pennsylvania, have refused to meet them in a joint conference such as has been customary in previous years. There are two reasons why the operators declined to hold such a meeting. In the first place, the last time they held a meeting of this kind they were all indicted under the Sherman Act for making an agreement in restraint of trade. In the second place, the miners at their convention did not authorize their delegates to negotiate a new contract, but instructed them that nothing less than a scale based on the present wage, with the addition that there should be a six-hour day, a five-day week, time and a half for over time, and double time for Sundays, would be accepted. These additions would very much increase the cost of coal over the present wage scale. The operators could not consider renewing a contract on the present scale, as it would mean ruin for them, and as the miners were not authorized to negotiate a new scale on a fair basis that would enable the operators to mine coal in competition with the open-shop mines the operators did not feel that there was any use in meeting the delegates.

Thirty per cent. of the output of bituminous coal comes from the open-shop mines of West Virginia, Alabama and Pennsylvania. During the strike in 1919, this 30 per cent. was increased to 50 per cent. and it has affected the operations of the union mines to such an extent this year that they have been able to run only 15 to 30 per cent. of their time, while the open shop mines have run from 60 to 80 per cent. as the wages in these mines had been reduced to the 1917 scale.

The operators in Illinois and in Oklahoma have met with the miners and offered to negotiate a new scale, but the miners have advised them that they were without authority to make any scale of wages until the basic scale had been arranged in the four competitive states. The situation from the miners' union point of view is that they are not organized for any reduction of wages. Their organization is successful as long as they can continue to advance wages, but any retreat from the high wage scale which they have now acquired would cause dissatisfaction in the rank and file and probably the loss of leadership to the men who are now at the head of it. The proposition, therefore, is a simple one—the miners' leaders have put the scale on such a basis that the operators can not agree to it and when the present stocks of coal are exhausted they are confident that the Government will step in and form a commission which will arbitrate the differences, and if this commission should, as it probably would, insist on a lower wage scale the leaders of the miners could save their face by showing to the rank and file that the reduction was forced by the Government and not through their own negotiations.

### Operators Have Offered to Meet Miners

There is a probability, therefore, of a complete cessation of mining in the union fields until the present stocks are exhausted—possibly in 90 days—and then the real battle will begin; and the outcome of it depends entirely upon what action Washington may take. It has been claimed that the operators have gone into this fight for the purpose of breaking up the unions. There are no facts to sustain such a statement, as the operators in Oklahoma and in several other states have offered to meet their men and negotiate a scale, but the miners advised them that they were without authority to do so.

The only scale that will continue to be negotiated is the one in the anthracite region. Here the operators and the miners are both organized and have been since the Roosevelt Strike Commission which settled the five-month strike in that region in 1902. Their findings have formed a most valuable basis for negotiations; and decreed that all future disputes should be settled by a conciliation board consisting of three miners and three operators with a referee appointed by the court; that no suspension of mining would be permitted, but that any disputes must be presented before this conciliation board and if they were not able to agree it should be referred to the referee, whose decision should be final, and the award become retroactive to the date of the filing.

* Address before Tulsa Chamber of Commerce, March 31, 1922.

Digitized by Google

This has practically prevented any serious strikes in the anthracite region since 1902, and these same members of the conciliation board, consisting of the three presidents of the three districts in the anthracite region and three operators, form the board that is now negotiating for a new wage scale. Two years ago they tried to negotiate a wage scale starting the ninth of March. No decision was arrived at although the discussions continued until the middle of September. An agreement, however, was made that the miners would continue at work and whatever award was made become retroactive to the first of April. Failing to reach any agreement in September, the Government appointed a commission which granted an award giving 20 per cent. advance in wages. The miners are now asking for another 20 per cent. advance and in order to meet this latter demand the anthracite operators have prepared themselves with facts through an entirely neutral and independent source; namely, the Federal Board of Industrial Research, which has made a careful study of the anthracite situation with comparisons between the wages and living conditions in 1921 and 1914. It finds that the increase in wages has been 160 per cent. to the anthracite miners as against 131 per cent. for the railroad men and 120 per cent. to industrial workers. Taking it on the basis of the cost of living and deducting the higher cost of living in 1921 as compared to 1914, it shows that the actual increase in wages has amounted to 60 per cent., and this figure is further checked by the savings accounts of the various banks in the anthracite region, which showed an increase of $75,000,000 during the last two years.

### Coal has Become a Luxury

There is no question, therefore, that the present wage in the anthracite region is more than ample and any advance over that would mean another increase in the cost of coal to the consumer. The anthracite operators have taken the position that they are willing to make a fair working agreement with their men to pay them a fair living wage, but that there must be a reduction from the present wages as they are now too high and the coal has become too expensive. It is considered a luxury rather than the necessity it should be for the people in the East who use that coal exclusively. Anthracite is used by the working people as well as by others and they should be furnished with coal at a reasonable price, which can not be done under the excessive wage that is now being paid.

In the bituminous field the basic wages are even higher. In Oklahoma outside day labor has been increased from $2.25 to $7.50. It is claimed that the high wages are needed on account of the short running time, but this is largely due to the high wage, which has made the cost for the coal so great that the territory in which it can be distributed has become restricted by the competition of the open-shop mines in Alabama and Colorado. The operators in Oklahoma can not afford to continue to pay the same wage and compete with the mines in surrounding states, and the people of Oklahoma are entitled to receive a cheaper coal which can be furnished only by the deflation of the miners' wage corresponding to the deflation which has already taken place in the earnings of the farmer, the metal miner, and, in fact, of workers in nearly every industry except that of coal mining.

This country must get back to work. It must return to a normal basis and it is not right that the farmer, the merchant, the professional man should have his living costs increased by the high price of fuel in order to maintain a wage higher than even the war wage to a certain class of miners. The cost of coal enters into the cost of nearly everything that is produced and it enters also into the cost of marketing the product of the farms, as fuel is one of the heavy expenses of railroads; a reduction in the cost of fuel is necessary as well as a reduction in the wages of the railroad men if freight rates are to be put back to a normal basis.

### Government Expected to Pay Losses

The facts in this case do not seem to be thoroughly understood. I think that if they are known, the public will not sympathize with the demands of the miners, and without public sympathy no strike can be successful It would be the part of wisdom to conserve as far as possible what coal supplies are now on hand, as the duration of the strike is very uncertain. It would be a misfortune if the Government should intervene, as it would be much better if the questions that are now at issue could be settled directly between the miners and the operators. We have had too much government intervention in business and every intervention of that kind has meant disorganization and higher costs.

The great desire of the miners is that the coal mines should be nationalized. I asked one of the district presidents why it was that they were so insistent on the nationalization of coal mines, when they could see that the nationalization of the railroads had not been a success and coal mines were more difficult to operate than railroads. The district president agreed with me that such was the case, but he said: "At the same time, the Government has given high wages and short hours to the railroad men and that is what we want, and we know that if the coal operators give us the short hours and high wages that we ask their overhead will be so great that they can not sell the coal at a price the public would be willing to pay, but if the Government will take over the mines they can sell the coal at any price they please, for the United States Treasury is strong enough to pay out any difference between cost and selling price." This socialistic argument is extremely dangerous; the whole country should appreciate this, and should put its stamp of disapproval on any tendency toward nationalization or toward Government intervention in the management of a basic industry of this country.

## Gas Absorption and Oxidation of Non-ferrous Metals*

BY B. WOYSKI AND JOHN W. BOECK, BUFFALO, N. Y.

MANY writers, in discussing defects caused by oxidation and gassing of bronzes and red brasses advocate substantially the same cure for both. But from its nature, oxidation cannot take place if there is an excess of fuel in the furnace, while the gases absorbed by some alloys are products of incomplete combustion of the fuel. Hence the metal can be either oxidized or gassed, but it is doubtful whether these actions can take place simultaneously.

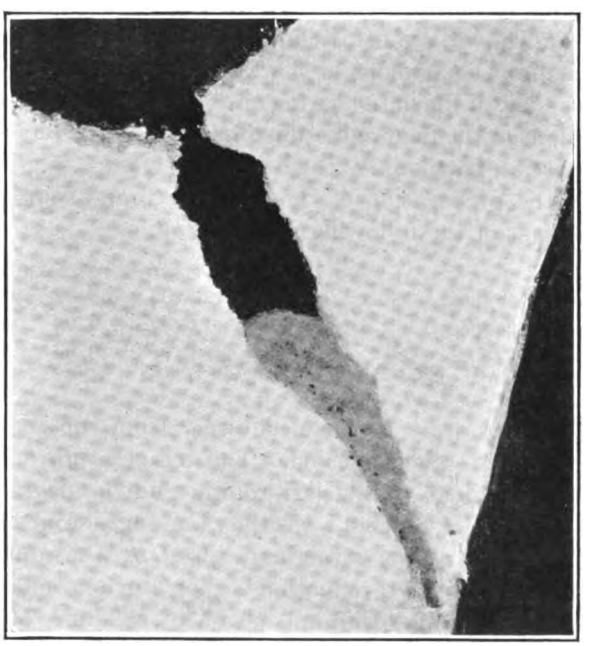
Oxidation can be easily overcome by the use of deoxidizers or it may be avoided by protecting the molten metal with suitable fluxes. Absorption of gases is more difficult to overcome. The regulation of the air and fuel, so as to produce complete combustion, and the protection of the bath by mineral fluxes are the most important factors. Gas expulsion, resulting in gas holes, porosity, unsoundness, and swollen or cauliflower-headed risers, is said to have several causes. One writer lists the most common causes in the order of their importance, as follows: Superheated metal, dirty or slaggy furnace conditions, using metals low in quality or those previously subjected to bad melting practice, poor grade of fuel, use of newly lined or damp ladles, indiscriminate mixing of scrap or illogical combinations of metal.

Superheating the metal usually occurs when the heat is ready to be poured but for some reason must be held in the furnace. In this case, a careful furnace tender tries to avoid overheating the metal by keeping a mild fire; that is, a reducing fire which, unfortunately, results in gassing the metal.

A dirty, slaggy furnace may result in gassing the metal by retarding the heating and prolonging the time necessary to bring the metal to the proper temperature, thereby increasing the chances of gassing in uncertain furnace atmosphere.

It is doubtful whether metals of low quality have anything to do with gassing molten metal, except possibly metals containing sulfur. The sulfur may produce gas holes as a result of a reaction with occluded oxides. The reaction between sulfur and copper oxide is reversible, depending on pressure and temperature.

Metal that has been subjected to bad melting practice, whether oxidized or gassed, can be brought back to normal conditions by proper furnace practice. In the case of oxidized metal, a deoxidizer or a flux is necessary. In the case of gassed metal, a strongly oxidizing furnace atmosphere of relatively high temperature, so as to produce quick melting, will correct the gassed condition. This has been proved many times. In one case, when, on account of a change in the furnace tender, several heats of red brass were gassed, all the castings were returned to the furnace and melted under the conditions just described, the resulting castings were entirely satisfactory, both as to fracture and microscopical examination.



LONGITUDINAL SECTION OF RISER OF A LARGE CASTING, SHOWING EXUDATION OF TIN-RICH ALLOYS.

The use of newly lined and damp ladles may be one cause of gassing. This may be ascribed to hydrogen, from dissociated steam, being absorbed and then liberated on freezing, or after action on the occluded oxides with the formation of steam at lower temperatures; although the dissociation of steam at the pouring temperature of bronzes is negligible.

* Rochester Meeting, June, 1922.

Digitized by Google

Indiscriminate mixing of scrap and the illogical combination of metals should never occur in any foundry, but we hardly believe that it would result in gassed metal.

From these practical observations it can be concluced that:

The most important cause of gassing molten metal is the furnace atmosphere. Gassed metal can be brought back to normal condition by remelting in an oxidizing atmosphere. A reducing atmosphere is more troublesome than an oxidizing one. Defects caused by gas or shrinkage may have a similar appearance to those caused by oxidation and are often mistaken for such.

## Physical Properties of Cartridge Brass*

By C. Upthegrove and W. G. Harbert, Ann Arbor, Mich.

During the past year considerable work dealing with physical properties of cartridge brass was done at the University of Michigan in cooperation with the Ordnance Department of the U. S. Army. This paper gives some of the data bearing on the effect of the anneal, previous to the final reduction or rolling, on the physical properties, particularly the hardness.

In the preparation of the cartridge brass, four bars were cast of the following composition:

| | No.1 | No.2 | No.3 | No.4 |
|---|---|---|---|---|
| Copper, per cent | 68.42 | 68.09 | 68.54 | 68.45 |
| Lead, per cent | 0.03 | 0.02 | 0.02 | 0.02 |
| Iron, per cent | 0.02 | 0.03 | 0.02 | 0.03 |
| Zinc, per cent | 31.53 | 31.86 | 31.42 | 31.50 |

The bars were overhauled direct from the casting shop, rolled and annealed. The temperature of the anneal previous to the last rolling and the degree of reduction, 37.1 per cent., was the same for all four bars.

The difference in structure caused by the anneals previous to the final reduction is shown in photomicrographs. Following the anneals at 570°, 650° and 750° C. the bars were all rolled to 0.134 in. Following the reductions, the bars were cut into 10- by 1-in. strips. From this point the annealing treatment was similar to that used by Bassett and Davis, the bars being annealed at 50° intervals from 200° to 750° C. and at 25° intervals from 250° to 325° C. A 3-in. piece was cut from each bar, for microscopic examination and Brinell tests.

### Conclusions

For low-temperature anneals, following reduction by rolling, the Brinell hardness of cartridge brass is appreciably influenced by the anneal previous to the rolling.

This influence decreases as the degree of reduction in rolling is increased.

For low-temperature anneals following reduction by rolling, the tensile strength and elongation are influenced, though to a lesser degree than the Brinell hardness, by the anneal previous to the rolling.

For cartridge brass annealed at temperatures of 650° C., or above, after reduction by rolling, the Brinell hardness, tensile strength, and elongation are independent of the anneal previous to the rolling.

* Rochester Meeting, June, 1922.

## Some Electrical Properties of Nickel and Monel Wires

By M. A. Hunter, F. M. Sebast, and A. Jones, Troy, N. Y.

This paper gives the results of an investigation of the specific resistance and temperature coefficient of the electrical resistance of nickel and its important alloy, monel metal. For most of the pure metals, the temperature coefficient of resistance is approximately 0.0004 per degree centigrade at 20° C. Nickel and iron, however, are exceptions. This property is important as it gives good material for the construction of thermometers and other instruments involving electrical control.

A summary of information on this subject has been published by the Bureau of Standards. The present experiments antedate this publication by several years and as the information obtained is not contained in it, the results of the experiments are published as additional information.

These experiments indicate the conditions that must be observed to secure a nickel wire with the highest possible temperature coefficient of electrical resistance. The nickel must be the finest available. The additions of manganese must be as small as compatible with subsequent forgeability. The time taken to melt should be a minimum, in order that the molten material shall be exposed for as short a period as possible to the effect of furnace gases. If these conditions are met, a high-grade nickel wire can be readily produced.

### Commercial Alloys of Nickel

Malleable nickel ingots are produced in several grades. The most important are grades A, C, and D nickel. In view of the fact that nickel has a high temperature coefficient at low temperatures and also a high resistance to oxidation at high temperatures, it was thought advisable to investigate the temperature coefficient of the material at high temperature. To this end, the resistances of samples of these various materials were measured over the range from 20° to 1000° C.

Monel metal, an alloy containing 67 per cent. nickel, 28 per cent. copper and 5 per cent. other metals (chiefly iron, manganese and silicon) is similar to nickel in that it has a high temperature coefficient, so a sample of this material was subjected to the same investigation. Exact analyses of the materials used are not at present completed, but will be added to the report.

Digitized by Google

SUMMARY

Pure nickel with a low specific resistance and high temperature coefficient may be produced by melting electrolytic nickel with the addition of a minimum amount of manganese. The time for melting is a material factor in the production. The effect of various impurities is also indicated.

The variation of resistance with temperature for various grades of commercial nickel and of monel metal were investigated and from the resistance temperatures curves, the transformation points were obtained.

## Occurrence of Blue Constituent in High-strength Manganese Bronze*

BY E. H. DIX, JR., DAYTON, OHIO

DURING an investigation on high-strength manganese bronze by the Engineering Division of the Air Service, at McCook Field, Dayton, Ohio, particles of a "blue constituent" were noted in the microstructure of most of the bronzes examined.

The constitution of the simple copper-zinc base alloy is still a matter of dispute in spite of the fact that the copper-zinc series is one of the oldest industrially important groups of alloys, and has received the early consideration of scientific research. The diagram according to the most recent work, is shown in the original paper.

The disputed questions involve termination of the beta field and the line at 470° C. The earliest experimenter, Roberts-Austin, detected an arrest in some of his cooling curves at approximately this temperature and ascribed them to the formation of a eutectic; it has since been proved that there are no eutectics in this series. Shepherd was unable to detect any thermal arrests at this temperature; his diagram was essentially as shown, except that the line at 470° C. was omitted and the beta phase carried down to normal temperatures. Later, Carpenter and Edwards, by a very painstaking research, definitely established the authenticity of the line but attributed it to the breakdown of the beta constituent into a eutectoid of alpha and gamma. Microscopic evidence of the formation of the eutectoid is doubtful and it seems more likely to be due to an allotropic change in the beta constituent. At least for practical purposes, it is more convenient to think of the structure of a 60–40 brass as a mixture of alpha and beta prime crystals rather than alpha plus an unresolvable eutectoid of "apparent beta" as it has often been called.

Manganese bronze consists of a 60–40 copper-zinc base alloy, to which is added small quantities of each of the elements, tin, aluminum, iron, and manganese. Usually the percentage of any one of the elements added is so small that, if added alone, it would be taken into solution and the only effect on the structure would be to give more beta prime and less alpha than would be expected for the true zinc content. This effect can be satisfactorily estimated by the use of Guillet's "fictitious zinc" calculation. However, when even these small percentages of the four elements are added in the same alloy, the joint effect often produces small regular particles of a third constituent of a characteristic blue color. That these particles are much harder than the alpha-beta prime matrix is shown by an examination of the polished surface unetched. They stand out in relief. Contrary to the findings of the experiments previously reviewed, in which the appearance of a special constituent was accompanied by a severe reduction in the elongation, a moderate amount of this constituent is found in ductile manganese bronze (having an elongation of at least 30 per cent.) and a considerable amount is usually present in particularly high-strength manganese bronze (over 80,000 lb. per sq. in. tensile strength).

When the hardening elements (aluminum, tin, iron, and manganese) are added to the 60–40 copper-zinc alloy in sufficient quantities to produce a high-strength manganese bronze, a third constituent appears in the alpha-beta prime complex, which has a characteristic clear blue color.

The occurrence of this constituent in reasonable amounts is not necessarily accompanied by brittleness.

Annealing for 7¾ hr. at 1560° F., followed by either water quenching or slow cooling, does not cause the disappearance of this constituent.

This constituent, when examined unetched, appears to be of a deeper blue than either the delta constituent of the copper-tin series or the gamma constituent of the copper-zinc series. When etched with $NH_4OH$ plus $H_2O_2$, the blue constituent is unattacked except for a slight eating away at the edges under prolonged etching, whereas the gamma constituent with the same reagent is immediately tarnished and rapidly dissolved. The characteristic shape of the blue constituent is decidedly different from that of the delta of the copper-tin alloys.

For practical purposes in the study of the microstructure of manganese bronzes, it seems highly desirable to regard the blue constituent as distinct from either the delta or gamma, and it is suggested that it may reasonably be denoted as delta prime.

In the manufacture of manganese bronze, the particles of delta prime are precipitated from the copper-rich solid solution by the addition of the zinc. This precipitation is strongly influenced by the presence of iron and, therefore, the particles probably consist of a solid solution of iron and copper with or without some tin, aluminum or manganese.

# An Inventory of Results of Accident Prevention*

C. A. Allen, Salt Lake City, Utah

FOR over three years, we have been endeavoring to reduce the number of fatalities and minor accidents in Utah. The physical condition of the mines, concentrators, and smelters is good, yet the number of accidents, especially in the coal mines, has been much higher than it should be; though compared with all the mines of the United States, the metal-mine accident rate has been good. This has been a source of wonder to us; we are proud of the physical condition of our coal mines, just as much as of our metal mines, and have a number developed along the most modern lines. We believe that, taking the state as a whole, we have just as good coal mines as any state in the Union.

Considering the efforts in safety work during these years, conditions do not show the improvement they should. Every fatality in Utah is investigated by a mine inspector, and their reports were carefully gone over in an effort to place the responsibility for the deaths. Out of 57 fatalities in the mines, quarries, mills, and smelters, in 1919 and 1920, the responsibility could be placed about as follows:

| | Open-pit Mines and Quarries, Per Cent. | Underground Mines, Per Cent. | Mills and Smelters, Per Cent. |
|---|---|---|---|
| Fatalities due to conditions that could have been avoided by companies | 30 | 6½ | 30 |
| Laxness of foremen or bosses, in some cases shared by man killed | | 16 | |
| Fault of fellow employees | 40 | 6½ | |
| Carelessness of man killed | 10 | 29 | 20 |
| Purely accidental | 20 | 42 | 50 |

Out of 63 fatalities in the coal mines in 1919 and 1920 we placed the responsibility as follows:

| | Per Cent |
|---|---|
| Fault of man killed | 39 |
| Due to conditions that could have been avoided by company | 9 |
| Fault of fellow employee | 11 |
| Purely accidental | 41 |

Some of the largest mines had comparatively low accident rates, but most of them had more efficient safety inspection and instruction and had steady employees, which outweighed the advantages of the smaller mines.

During 1920, accidents were more numerous than in the years preceding or following. For most of the year, men were not plentiful, there was a large demand for coal, and the men were making extremely high wages.

A careful study of the results shown, by investigation and collection of data taken in conjunction with other information, led to the following conclusions:

1. The men are responsible for most of the accidents and efforts to reduce the number of accidents must take this fact into consideration. While there is a large proportion of good, careful, efficient, conscientious workmen, too large a percentage of the men, unfortunately are not of this type and they are the ones toward whom our efforts must be directed.

2. A mine, or more especially a plant, having the best physical condition may have the highest accident rate. When a plant is well provided with safeguards, there is a tendency for some men to become careless and to consider the safeguards as an excuse for less care and sometimes as an object of ridicule.

3. Other things being equal, small mines have proportionately fewer accidents than large mines.

4. The efficiency and ability of the mine management is one of the most decisive factors in the prevention of accidents. When a good foreman can maintain proper discipline regarding safety measures, accidents will be few.

5. Since the passage of compensation laws by the various states, there has been a marked increase in the number of minor accidents reported. While the great benefit of these laws has been most thoroughly proved, men of a certain type have taken advantage of the laws to lay off from work when they would not have done so if they were not to receive compensation. It is also not unreasonable to assume that the knowledge that they will receive a monetary consideration if they are injured has a tendency to make some men more careless.

6. When labor is scarce and wages are high too many men will refuse to recognize safety regulations and accidents increase.

The number of fatalities in mining in Utah during 1921 was lower per thousand employed than the average of the last seven years. No doubt, some credit must be given to this safety campaign; it enlisted the efforts of the foremen and the good miners, and due to the plentiful supply of men, the foremen were enabled to enforce strict discipline. This was also the first year in which the coal mines were brought up to the standards of the new safety regulations accepted by the operators and the state in 1920. The results of a campaign of this kind, however, are but transitory, and something more permanent is necessary. Training of a large percentage of our miners is imperative before accident prevention will attain its ultimate success; the methods for doing this have not been fully developed. The following methods seem the most likely to result in success:

1. The principles of safety and efficiency should be inculcated in the minds of the school children in the mining camps; also the spirit of taking pride in their work.

2. The apprentice system should be adopted wherever the conditions of the work will permit. By paying the apprentice less money, the skilled man may receive more without increasing the total cost of the products.

3. In British Columbia, a man must pass an examination before he can work as a miner and receive first-class

* New York Meeting, February, 1922.

Digitized by Google

miners' wages; this is essentially the apprentice system applied underground.

4. Probably the most effective way to train men and get immediate results is through the foreman and any way of increasing his knowledge or his ability to impart it is a step in the right direction.

---

## Systems of Mining in Pocahontas Coal Field and Recoveries Obtained*

By Thomas H. Clagett, Bluefield, W. Va.

THE Pocahontas coal field comprises the area in Tazewell County, Va., and Mercer and McDowell Counties, W. Va., in which Nos. 3 and 4 Pocahontas seams of bituminous coal are mined. It is a mountainous region with ridges rising 300 to 1000 ft. above the very narrow valleys and, except some poorly kept farms along the tops of the ridges and the area occupied by the mining and coking plants and villages, is wooded throughout.

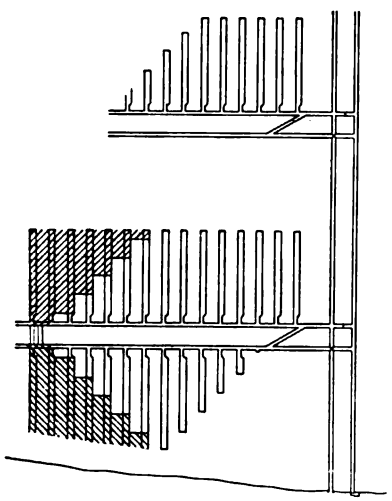

Fig. 1.—System of mining forming part of early leases.

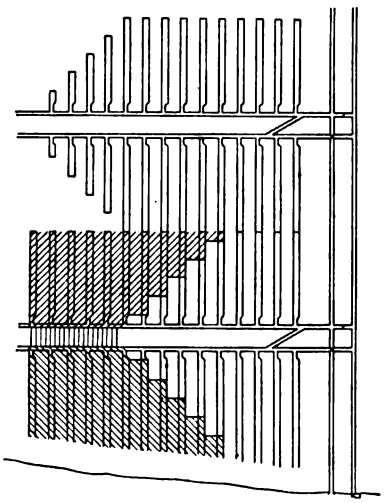

Fig. 2.—Second system of mining used.

No. 3 seam is from 4 to 10 ft. thick, but the change is gradual and the thickness fairly uniform in any particular locality. It has a streak of bone, about 2 in. thick, to which the coal adheres on both sides. In parts of the field this bone is replaced by hard slate, usually from 2 to 4 in. thick. The seam has a slate or fireclay bottom and a draw-slate top.

No. 4 seam is from 65 to 80 ft. above No. 3 seam, and of minable section only in the western part of the field. It is from 3 to 8 ft. thick and has two streaks of bone, each from 1 to 2 in. thick. It has a fireclay or slate bottom and is overlaid by from 4 to 24 in. of a laminated coal and slate, locally termed "black rash," which is separated from the coal seam by about 3 in. of slate. This "black rash" averages about 25 per cent. ash, but contains some clean coal.

The coal in both seams is quite soft. Cleavage sufficiently well defined to exert an influence on the mining is rare. Overlying strata are slates, shales, and sandstones, the sandstones predominating, extending from 30 to 1000 ft. above No. 3 seam. The strata directly above the draw slate of No. 3 seam, or "black rash" of No. 4 seam, and up to the first sandstone are usually slates or shales, about 10 ft. thick over the thicker coal, decreasing in thickness as the coal becomes thinner, and sometimes disappearing altogether. The dip of the seams is usually sufficient to provide natural drainage, although there are many undulations, swags, and basins requiring pumping and ditching. Explosive gas is rarely found except in the slope and shaft workings. The land as a rule, including the surface, is owned by land-holding companies and leased to operating companies on a royalty basis.

### Mining Method Used

The room-and-pillar system of mining has been used from the beginning, the principal changes in the manner of its adaptation as mining progressed are shown by the accompanying sketches. Fig. 1 shows the system of mining that was made a part of many of the earlier leases. It provided that entries and break throughs should be 10 ft. wide, entry pillars 60 ft. wide, rooms 18 ft. wide, and room pillars 42 ft. wide; that rooms from one entry of a pair should be turned and worked out progressively on the advance; that rooms from the other entry should be turned and worked out progressively on the retreat; and that pillar mining should be deferred until the entries had been driven the intended distance and then begin in the last pillars and conducted on the retreat in both sets of pillars, the chain pillar of the entry being

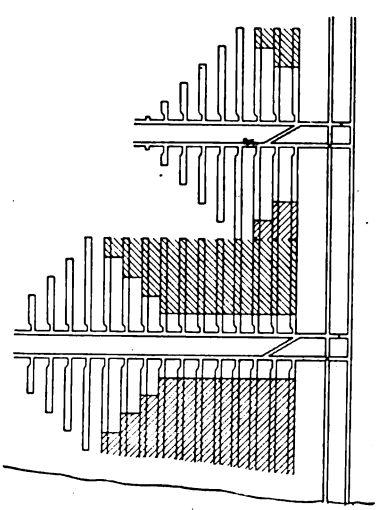

Fig. 3.—Drawing pillars on the advance.

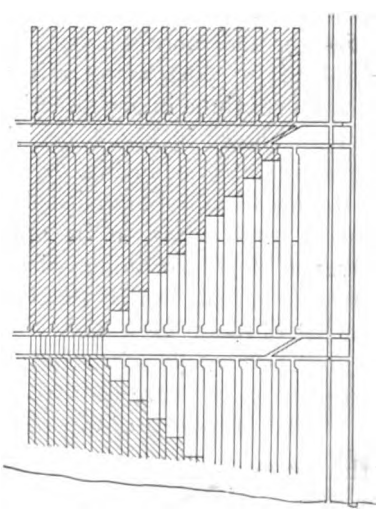

Fig. 4.—Pillar-drawing method used later.

* New York Meeting, February, 1922.

Digitized by Google

mined at the same time. In but few instances was this system carried out, apparently because of the desire for immediate tonnage.

The first change was to work out rooms from both entries on the advance (Fig. 2); with few exceptions this system was followed for a number of years.

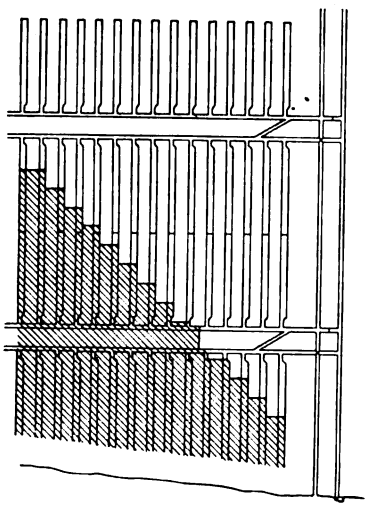

FIG. 5.—PILLAR-DRAWING METHOD USED WHEN GRADES ARE FAVORABLE.

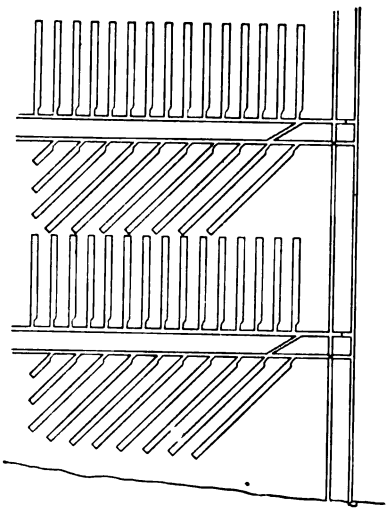

FIG. 6.

An effort was made to avoid the losses and inconvenience caused by the delay in pillar mining by mining pillars on the advance, as shown in Fig. 3; but, unless the rooms were unusually long and the cover light, the area opened was not sufficient to cause a break of the overlying sandstones and a squeeze usually followed. This caused a loss of the entry stumps and chain pillar and the squeeze spread to adjacent areas when opened up.

Longer and more uniform break lines were obtained by postponing pillar mining until it could continue in one direction over a larger area, as shown in Fig. 4, or, when the grades were favorable, as in Fig. 5.

Rooms from both entries of a pair not only caused large areas to be opened up far in advance of pillar mining, with probability of losses as stated, but frequently required that one set of rooms be worked to the dip, or else at an acute angle with the entry, in an attempt to keep above the strike line, as shown in Fig. 6. Progress of dip rooms was usually delayed by water while changes in direction of rooms caused irregular break lines in pillar mining. The working of rooms from both entries of a pair was therefore discontinued, as a general practice, in favor of working rooms from one entry only (see Figs. 7 and 8), and although many mines continued to turn and work all rooms on the advance, others first drove room entries to completion and then turned and worked out the rooms progressively on the retreat, followed promptly by pillar mining as indicated.

There were other changes from time to time and a variety of combinations as regards width, length, and spacing of rooms, but experience and a study of methods of other fields had shown that economical pillar mining and a maximum recovery of coal required that rooms be opened up only fast enough to provide for the uninterrupted advance of pillar mining; that pillars be mined promptly upon completion of rooms; that the line of pillar mining be carried forward uniformly in one direction until sufficient area was completely mined out to cause a good break of the overlying sandstones; that the direction of the break line be varied as little as possible, within reasonable limits, and that barrier and other pillars be of sufficient size not only to protect the workings properly but to admit of their being satisfactorily mined later. Most new development since 1900 has been laid out with these principles in mind.

## An Outline for Papers on Mining Methods. Compiled by the Mining Methods Committee*

THE Mining Methods Committee during the past year has spent much of its time developing the interest of members of the Institute in the work that comes under its direction. The response on the part of the membership has been most encouraging and in order to give a concrete form to the program which it hopes to develop, an "Outline for Papers on Mining Methods" has been drawn up and submitted for consideration. This outline has slowly taken shape until it represents ideas contributed by a great many men, and it is hoped that it will be suggestive and helpful in the preparation of papers.

# Personal Notes and Biographies

**Frank Maloit, Jr.** is with the Empire Zinc Co. at Gilman, Colo.

**E. L. Miller, Jr.** is teaching at the Missouri School of Mines, Rolla, Mo.

**Arthur L. Endress** is with the Spar Mountain Mining Co., Cave-in-Rock, Ill.

**B. W. Knowles** is superintendent of the Nickel Plate mine, at Hedley, B. C.

**Louis B. Benton** is geologist with the Humble Oil & Refining Co., Ardmore, Okla.

**Herbert N. Witt** is consulting geologist with Thebo, Starr and Anderton, San Francisco.

**Earle G. Morgan** is assistant general manager of the Abangarez Gold Fields of Costa Rica.

**C. L. Boeke** is with the San Francisco Mines of Mexico, Ltd., at Parral, Chih., Mexico.

**John A. Quigley** is at Camp Verde, Ariz., with the Yavapai County Highway Commission.

**Edel Moldenke,** of Watchung, N. J., is with the Southern Spar & Mica Co., Swannanoa, N. C.

**Arthur L. Harris** has returned from La Vega, Dominican Republic, and is now at Dillsboro, N. C.

**D. A. Powell** is in the diamond-drilling department of the Cortez Oil Corpn., at Tampico, Tamps, Mexico.

**David D. Irwin** has left Mexico and is now with the Phelps-Dodge Corpn,. Copper Queen Branch, Bisbee, Ariz.

**Richardson T. Wilder** is superintendent of the Mazapil Copper Co., Ltd., Concepcion del Oro, Zacs., Mexico.

**Chester W. Washburne** lectured on the principles of oil geology at Harvard University during the last week of March.

**E. L. Beck** is a member of the firm of Siler & Beck, Engineers & Contractors, with offices in the Martin Bldg., Mexia, Texas.

**D. W. Butner,** who has been in the Belgian Congo for some time, has returned to the United States and is at Colorado Springs, Colo.

**S. Paul Ward,** recently returned from South America, is smelter superintendent with the Shasta Zinc & Copper Co., at Winthrop, California.

**C. W. Van Law,** recently with the Union Petroleum Co., Philadelphia, has opened an office for consulting work, in the Woolworth Bldg., New York City.

**Walter G. Perkins** and **Preston K. Horner** have opened an office for consulting work as mining and metallurgical engineers, at 62 London Wall, London, England.

**Dean E. Winchester** has opened a consulting office in the Ernest and Cranmer Bldg., Denver, Colo., to handle geological investigations of petroleum, oil shale and coal properties.

**Fletcher H. Wood,** who has been with the Transcontinental Petroleum Co., Panuco, Vera Cruz, Mexico, is now with the Cia. de Gas y Combustible Imperio, S. A. at the same place.

**Henry S. Burnholz** has been appointed mining engineer on the special drill-steel investigation being conducted under the joint supervision of the U. S. Bureau of Mines and Bureau of Standards.

**L. Reinecke** expects to begin practice in Johannesburg very soon, as a mining geologist and topographer. At present, his address is Ceres, Cape Province, South Africa, in care of Rev. D. M. Reinecke.

**Robert Linton,** chairman of the New York Section, was a guest of the Pittsburgh Section at a dinner on March 28. Later in the evening, Mr. Linton addressed the Mining and Metallurgical Section of the Engineers' Society of Western Pennsylvania.

**Alfred Paul Grossman,** formerly junior mining engineer with the Empire Steel and Iron Co. at its Mount Hope mine, New Jersey, is now with the Massachusetts Highway Commission, Department of Public Works, as resident engineer at Middleboro.

**Robert C. Stanley,** formerly first vice-president of The International Nickel Co., was recently elected president. Mr. Stanley has ordered a reorganization of personnel, involving as its chief feature a new department of Development and Research with headquarters at 67 Wall St., New York City. This department will be under the direction of **A. J. Wadhams,** as manager. Associated with him will be **Paul D. Merica,** director of research.

**B. Britton Gottsberger** has been elected professor of mining by the Yale Corporation and will assume his duties as a member of the Yale University faculty at the beginning of the academic year next fall. Since the resignation of Prof. James F. McClelland in 1919, there has been no professor of mining in Yale University.

Mr. Gottsberger was born in Brooklyn, in 1874; he

Digitized by Google

received his education at the Brooklyn Polytechnic Institute and at the School of Mines of Columbia University, where he received the degree of E.M. in 1895. After an unusually varied experience as assayer, surveyor and engineer in Central America and Mexico, Mr. Gottsberger went to the Tennessee Copper Co. in 1900, and ultimately rose to the position of general manager. In 1909, he became general manager of the Miami Copper Co. He resigned that position in 1919, to engage in consulting work, and since August, 1921, has been secretary of the Mining and Metallurgical Society of America.

Few men have to their credit as brilliant a managing record as he has established during his 20 years of experience in the management of big companies. He is considered by those who have been intimately associated with him as one of the best qualified American mining engineers who could be chosen for the task of developing a department in Yale University.

**E. C. Reeder,** for the past five years chief engineer of the Rosiclare Lead and Fluor Spar Mining Co., at Rosiclare, Ill., resigned that positson on March 1, to enter the employ of the Hillside Fluor Spar Mines, of the same place, in a similar capacity.

## Samuel McClure

SAMUEL McCLURE, second vice president and general manager of the Stewart Furnace Co., and for nearly half a century identified with the iron and steel industry in the Shenango Valley, died at his home in Sharon, Pa., on March 25.

Mr. McClure was born on Jan. 3, 1839, in Little Beaver Township, Beaver County, Pa. His father was a merchant contractor and farmer, his mother was the daughter of Samuel and Mary (Custer) Clark, of the same family as the famous General Custer.

Samuel McClure received a public school education, and attended Girard Academy, at Girard, Pa. He started work on a farm and also clerked in his father's store. In 1862, he entered the employ of James Wood and Son of Pittsburgh and was sent by that firm to its Homewood furnace, Lawrence County, to take over the management of a store.

In 1863, Mr. McClure's career in the iron and steel industry began as cashier, bookkeeper and later superintendent and manager of the James Wood & Son Company's furnace in Wheatland, Pa. He remained in Wheatland until 1873, when he went to West Middlesex to manage a blast furnace.

In January, 1874, he went to Sharon as superintendent of the Stewart Iron Co., Ltd., which about a year ago became the Stewart Furnace Co. He acquired an interest in the company in October, 1889, and was elected to the board of managers. He was also general manager of the iron business of the company in the Shenango Valley and of the coking interests at Uniontown, Pa. During the same period he was made president of the Shenango Machine Co. of Sharon.

In association with the late F. H. Buhl and the late Daniel Eagan in 1886, Mr. McClure assisted in the organization of the Sharon Steel Casting Co. and was elected vice president. This company was later acquired by the American Steel Casting Co., which in 1902 became a constituent company of the American Steel Foundries.

Until the merger of the Sharon Savings & Trust Co. with the McDowell National Bank several months ago, Mr. McClure was president of the former banking organization. He had been a member of the Board of Directors of the Savings & Trust company since its early history.

Mr. McClure was also president of the Sharon Railway Co., president of the Union Limestone Co., of Youngstown, O., president of the Board of Trustees of the F. H. Buhl Farm, president of the Christian H. Buhl Hospital.

Mr. McClure was a staunch Republican and representative of the then Forty-seventh District as State Senator in 1884.

He was a member of the American Institute of Mining and Metallurgical Engineers, and of the American Iron and Steel Institute.

He was married on July 1, 1863, to Augusta R. Dickson of Clarksville, Pa. Mrs. McClure died in 1921.

Surviving are three daughters: Mrs. Charles F. Phillips, and Mrs. C. C. Marshall, of Sharon; Mrs. D. M. Forker, of Cincinnati, O.; one brother, Thomas McClure of Meadville, Pa.; two sisters, Mrs. Frank Jones and Miss Sara McClure, both of Clarksville, Pa., and ten grandchildren.

## Philip Argall

PHILIP ARGALL, on his father's side, was descended from a Cornish mining family; his mother was Scotch-Irish. He was born in Newtownards, County Down, Ireland, in 1854, came to America in 1887, and was naturalized in 1889.

Mr. Argall finished grammar school when he was sixteen, and went to work in the dressing works of the Tigroney mine. He studied mathematics and surveying under a tutor, and was given friendly help by professors at the Royal College of Science for Ireland, in Dublin, who were interested in his ambition. When he was 20 years old, he bought a second-hand laboratory equipment, and in 1879 he took a course in metallurgy at Swansea, Wales. He also worked at all kinds of mining, and in 1875 was assistant manager of the Cronebane mine, with the title of Captain, according to Cornish practice.

After varied experience in metallurgical plants and mines in Ireland, Cornwall and Wales, he went, in 1883, to New Zealand, as manager of mines at Coromandel

Digitized by Google

for the Kapanga Gold Mining Co. He spent about a year in New Zealand, then made some examinations in France, and in 1886 became superintendent of the Los Bronces and Animas mines in Mexico.

At the end of 1886, he became consulting engineer to the Mountcashel Iron Ore Co., Antrim, Ireland; also to the Société Anonyme de Plomb d'Aspérières, operating on the river Lot, France. He was working on a concentrating mill for the former when he was offered the position of manager of La Plata smelter at Leadville, Colo., in March, 1887.

Mr. Argall's work after he came to the United States was in various fields of mining and metallurgy. He traveled extensively in Mexico, from 1903 to 1907, and in 1905–06 had charge of the field work of the Zinc Commission appointed by the Government of Canada to investigate the zinc resources of British Columbia and test the ores to determine the best commercial process for their beneficiation.

In 1876, Mr. Argall married Miss Frances Oates, of Avoca, Ireland. They had five sons, two of whom formed a partnership with their father several years ago, under the name of Philip Argall & Sons. The offices of the firm were in Denver, Colo.

Mr. Argall died on March 19, 1922.

## Knox Taylor

KNOX TAYLOR, president of the Taylor-Wharton Iron and Steel Co., died at his home in High Bridge, N. J., on April 4. He was of the fifth generation of his family in the management of the industry which was founded in 1742.

Mr. Taylor was born at High Bridge on Oct. 19, 1873, son of the late William Johnston Taylor and of Mary Alward Taylor. He began his education at Chester, N. J., where for a time his father operated an iron blast furnace; later he attended the Hill School at Pottstown, Pa., the Model School at Trenton, and was graduated from Princeton University with the degree of Bachelor of Science in 1895. In college he was a member of the track athletic and football teams, and was selected as all-American guard. His love of outdoor life led him to engage in mining engineering work in the Rocky Mountains for seven years after leaving college.

In 1902, he returned from the West to enter the employ of the Taylor Iron and Steel Co. He began at the bottom and worked up through various departments in the foundry and the old wheel shop, until he became general manager in October, 1905. Five years later he became president of the company.

In 1912, the Taylor company purchased all the interests of William Wharton, Jr. & Co., Inc., of Philadelphia, and its subsidiary, the Philadelphia Roll & Machine Co. and the combination became known as the Taylor-Wharton Iron & Steel Co. In 1913, the company bought out the interests of the Tioga Iron & Steel Co. at Philadelphia, an acquisition which proved of much importance during the war. Each subsidiary of the Taylor-Wharton Iron & Steel Co. retained its identity and Mr. Taylor was president of each.

During the war, in addition to the work of his company's own contracts, he helped supply railway track material for the American Expeditionary Forces, representing in the dealings with the Government all of the principal manufacturers of this class of product.

In 1903, Mr. Taylor was married to Lucy J. Miller, daughter of Llewellyn Miller of Baltimore, Md. Their children are Robert Knox Taylor, aged twelve, and Mary Summers Taylor, aged nine.

KNOX TAYLOR.

Mr. Taylor always kept up his keen interest in college affairs. In 1918 he was elected a life trustee of Princeton University; for many years he had been a member of the Board of Athletic Control and at the time of his death was chairman of the Football Advisory Committee.

He was deeply interested in all civic improvements. Foster M. Voorhees, in the *High Bridge Gazette* of April 6, says

> Every movement that tended to the betterment of the community and every agency already organized for that purpose had his cheerful and generous support. He aided and encouraged the many efforts put forth to make our community a better place in which we and those who follow us may live.
>
> A man whose aims were high, whose life was exemplary and whose character was noble, . . . our community is better for the life Knox Taylor lived.

Digitized by Google

He was responsible for the organization of the first Boy Scout troop in the town, in 1914. As interest developed he provided equipment and space in the community center under the direction of the Y. M. C. A. and helped to establish the camps at Lake Solitude. In the second year the camp was named for Mr. Taylor by unanimous vote of the boys. Later a girls' camp was added. Mr. Taylor was instrumental in placing at the disposal of the community the present site of Camp Taylor for use over an indeterminate term of years.

During the war Mr. Taylor was keenly interested in the conservation and development of the food supply and encouraged its production by the formation of the Farmers' Club and the allotment of company ground so that men and boys of the town could have a chance to raise their own farm produce.

Mr. Taylor was a member of the American Institute of Mining and Metallurgical Engineers, which he joined in 1897, and also of many other societies and clubs, including the Railway Business Assn., of which he was vice-president, Down Town Assn., Rocky Mountain Club, American Society for Testing Materials, American Chemical Society, American Society of Mechanical Engineers, Society for Promotion of Engineering Education, Princeton Engineering Association, and the Iron and Steel Institute of England.

## Harry Firmstone

HARRY FIRMSTONE, president of the Longdale Iron Co., of Longdale, Va., died in Philadelphia on March 10, in the 74th year of his age. He was unmarried, and had no close relatives.

Mr. Firmstone's father, William Firmstone, was one of the pioneers in the anthracite iron business; he was manager of the Glendon Iron Works at Easton, Pa. when his son Harry was born in 1849. In 1870, William Firmstone, with Ario Pardee, organized the Longdale Iron Co., and in 1873, Harry Firmstone, after his father's death, became general manager of the company. Harry Firmstone was educated at the Polytechnic Institute of Philadelphia, and had worked under his father and older brother, Frank, at the Glendon Works.

A local newspaper says:

> Not a Rockbridge man, his home on the border of another county, a Northern man by birth and rearing, Mr. Firmstone identified himself in the affections and esteem of the people in western Rockbridge in a way that few living outside the county have ever done.
>
> The institution of which Firmstone was the head had by its fairness and generosity and uniform kindness and consideration with all with whom it had dealt, earned and received an appreciation which has not been forgotten and will not be for a long time by the people of western Rockbridge.

*The Iron Age* prints the tribute of a Philadelphia iron merchant in which he says: "No man in the iron business was more scrupulous than Harry Firmstone in living up to his contracts and agreements."

## Reuben L. Lindstrom

REUBEN LEONARD LINDSTROM, who died at Montreal on Dec. 12, 1921, was born in Moline, Ill., Nov. 26, 1889. He was graduated from the University of Illinois, School of Pharmacy, in 1911, with high honors, receiving a prize for having the highest standing in chemistry. Later, he achieved much success as a commercial chemist.

In 1917, he moved to Montreal and became metallurgist for the various plants of the Canadian Car and Foundry Co. In July, 1919, he became superintendent of the steel foundry. His personality made him popular with employees and friends.

He leaves his wife and three small children.

## George J. Salmon

GEORGE J. SALMON, a mining engineer connected with the U. S. Bureau of Mines, died on March 1, 1922, at his home in Philadelphia. He was a graduate of the Pennsylvania State College and a member of the Rocky Mountain Coal Mining Institute as well as of the American Institute of Mining and Metallurgical Engineers.

At the time of his death Mr. Salmon was engaged in work pertaining to the leasing of Government coal land. Prior to this he had served as an engineer for the War Minerals Relief Commission. He had also seen service with the Copper Range Co. at Painesdale, Mich. and with various other companies in different parts of the country.

## Necrology

THE deaths of the following members were reported to the Secretary's office during the month Mar. 20, to Apr. 19, 1922.

| Date of Election | Name | Date of Death |
|---|---|---|
| 1876 | Akerman, Richard | 1922 |
| 1880 | Almy, William F. | |
| 1917 | Argall, P. H. | March 19, 1922 |
| 1912 | Best, William Newton | April 11, 1922 |
| 1905 | Bostwick, William A. | Feb. 4, 1922 |
| 1920 | Eastick, Thomas H. A. | March 7, 1922 |
| 1879 | Firmstone, H. | March 10, 1922 |
| 1915 | Johnston, Francis B. | Dec. 8, 1921 |
| 1891 | McClure, Samuel | March 25, 1922 |
| 1916 | McRae, A. L. | |
| 1905 | Polkinghorne, John | Nov. 1921 |
| 1887 | Richmond, William H. | March 14, 1922 |
| 1891 | Sjogren, Hjalmar | March 23, 1922 |
| 1897 | Taylor, Knox | April 4, 1922 |
| 1887 | Varden, Richard A. | |

## Chemists to Meet in France

THE third international chemical conference will be held in Lyons from June 27 to July 2, under the auspices of the National Federation of Chemical Association of France. The last excursion taken by those in attendance will take them near to Marseilles, where the second congress on industrial chemistry will be held from July 2–7.

# Institute Affairs

## A Democratic Institute

EVERY once in a while there comes a letter from a member scolding the directors for the undemocratic manner in which the affairs of the Institute are conducted.

Some years ago the Institute had grown to such a size and had undertaken to concern itself with so many special activities and branches of the profession that it became evident that better work could be done by distributing responsibility, and the directors more and more began to assume these responsibilities until now they carry on much of the serious work of the Institute.

The directors do not need scolding for operating on undemocratic lines; they know full well the desire of the members for a democracy and know that it is based on excellent reasons; they know that the future of the Institute depends on successful expansion in this direction and are constantly working toward that end.

The difficulty, then, is not one of convincing a "small coterie" in New York that they should give to those outside of this city a greater voice in Institute affairs and give the local sections more work to do, but it lies in the physical difficulty of getting the distant voice to express itself and of getting the sections to share in the work.

Wireless, the telegraph, or the mails do not take the place of the physical presence of the directors when a subject comes up for discussion, and though the distant director may vote on questions referred to the Board, it is impossible for him to have the benefit of discussions and familiarize himself with all phases of a question. Many questions demand immediate consideration and reply, precluding even the opportunity to hear from the distant member of the Board.

There are 24 members on the Board. During the year 1921, eight (one-third) of the members of the Board resided west of the Mississippi, in which territory resides about 38 per cent. of our membership. Geographically and numerically, the Board was, in its makeup, fairly representative of the membership, as much so as could be accomplished by any plan of election which has been suggested.

Unfortunately, election to the Board does not mean a corresponding participation in its work. Only rarely have the Central West members been able to attend a Board meeting, and the members from the Pacific Coast have come to meetings even less frequently.

During the year 1921, the 16 members of the Board from east of the Mississippi answered present on an average of six times, while the eight members from the West answered an average of less than once. The Eastern 62 per cent. of the membership had, during the year, representation at the Board meetings, as compared with the 38 per cent. Western membership, in the proportion of 96 to 6.

This is the unfortunate situation respecting which these several writers complain. It is not the undemocratic system of electing directors, but the fact that when elected the directors do not attend meetings. No one regrets this more than the "little coterie" in New York, who would most willingly throw work and responsibility upon the absent members.

If the critics of the present plan of elections would suggest some better plan, it would receive most respectful consideration, but constructive suggestions have not been forthcoming. The selection of directors is now and has been for years very largely in the hands of the members of those districts from which a director is to be appointed.

### Qualifications for a Director

The chairmen of the Nominating Committees of the last few years have used every effort to ascertain the desire of the members, no name has been put on the ballot without extended correspondence.

Unfortunately the members of some districts have not been always mindful of one most important qualification among those that a director should possess; namely, his ability to attend meetings. This is really of far more importance than that he be a distinguished member of his profession whose activities keep him at home during the greater part of the year.

There are many distinguished members with homes in the West, whose business frequently calls them to the East; there are some who, while their business interests are in the West, have found it necessary to take up temporary or permanent residence in the East. Such men are perfectly capable of representing Western thought and among them are to be found excellent material for the Board.

Bearing in mind, then, not only a theoretical, but a practical democracy, it is urged that our Western members bear this suggestion in mind when next it is their privilege and duty to select representatives.

Digitized by Google

It may not be amiss to remind our members that in the early days the headquarters of the Institute were in the city where the secretary hung up his hat. The headquarters were frequently moved to all parts of the United States, but as the Institute grew it was found that some permanent home must be selected. A large donation was offered for a home in New York, but, before acceptance, the question was put to the vote of all members and the decision was unanimously in favor of a New York home. That has been decided once for all; whether the decision was wise or not is beside the question, but having been made, we must conduct our work as best we can in conformity with it. Suggestions looking toward improvement of the conduct of affairs are always welcomed and considered by the Board in the spirit in which they are offered.

There is one factor in the proper selection of directors that must be given serious weight. Nearly 30 per cent. of our members are primarily interested in metal mining, while the remaining 70 per cent. are primarily interested in one or the other of nine other branches of the mining industry. From this, it is evident that it would be very easy to name a directorate consisting almost or entirely of those whose primary interest is metal mining, while the other interests would be without adequate representation on the Board. In the past and with the system of nominations now in force, iron and steel, petroleum, coal and coke, geology, and other associated industries have been adequately represented on the Board. Any new plan of nominations must take into consideration the fact that democracy should apply to industry as well as to geography.

F. F. SHARPLESS.

## Summary of Directors' Minutes

AT THE meeting of the Board of Directors on March 24, 1922, there were present 10 directors, the secretary and assistant secretary, and 21 guests.

The committee appointed to consider the advisability of the participation of the Institute in an International Congress to be held in Philadelphia, in connection with the World's Fair in 1926, recommended that the Institute join with the other engineers in support of such a Congress; a committee was named to coöperate with similar committees from the other Founder Societies with this object in view.

The report of the treasurer and Finance Committee was presented and ordered filed.

There were elected 24 Members, 5 Associates and 33 Junior Associates; change of status, two from Associate to Member, two from Junior Associate to Associate; two members were reinstated; the name of Vincent Ferguson was added to the honor roll of senior members.

The By-Laws of the Southern West Virginia and the Northern Arizona Sections were approved.

Philip W. Henry, one of the representatives of the Institute on the Joint Committee on Code of Ethics for Engineers, read the report of that committee and the recommendations for putting such a code into effect. The substance of the proposed code brought forth discussion, as well as the procedure recommended by the committee, and two resolutions were passed: One, calling the code to the attention of members and asking them to give it consideration and advise the secretary in respect to any suggestions they might care to offer; the second calling for advice of counsel as to the legality of the proposed procedure.

An invitation was extended to the Mining Section of National Safety Council to hold a joint session at the 127th Meeting of the Institute in February, 1923.

The secretary reported the result of the postal card referendum as to relative interests in the classified subjects. Owing to the fact that returns on this referendum are still coming in, a final report cannot be rendered for some weeks. Publication will be made in MINING AND METALLURGY, so that all may be advised of the interests of their fellow members in the activities of the Institute. In the meantime, the classification is proving of great benefit to the directors and the officers of the Institute.

At the time of the February meeting, the City of Vancouver and the British Columbia Chamber of Mines extended an invitation to the Institute to hold its regular fall meeting in the City of Vancouver. Under instructions from the Board, the secretary made a preliminary canvass throughout the various local sections to learn what the sentiment would be toward holding a meeting in Vancouver. As a result of the canvass, the Board felt that it would be inexpedient to hold the fall meeting in Vancouver this year, and therefore instructed the secretary to regretfully decline the invitation.

The Executive Committee was empowered to select a place for holding the fall meeting of the Institute.

President Dwight announced the appointment of Messrs. George Otis Smith, H. Foster Bain, J. Edward Spurr, Pope Yeatman and the president ex officio, as a Committee on Industrial Preparedness, to coöperate with the War Department.

The matter of appointing a Committee on Education was referred to the Executive Committee with power.

The Committee on the Columbia Scholarship reported that the Woman's Auxiliary had selected Carleton B. Jansen, of Union College, Schenectady, as the beneficiary.

It was voted that the Board of Directors of the A. I. M. E. should request the American Engineering Standards Committee to designate the Institute as sponsor for the subject of Milling Standardization, experimental work upon which is now being conducted by the Committee on Milling Methods under the chairmanship of Dr. Galen H. Clevenger.

The Geological Club of Harvard University was admitted as an Affiliated Student Society.

A unanimous vote of thanks was extended to James

Digitized by Google

T. Grady and the Federated American Engineering Societies for the efficient manner in which the proceedings of the last annual meeting were brought to the attention of the public.

The appointments of chairmen of various technical committees was approved.

The Committee on Petroleum and Gas presented a petition to form a separate Division of the Institute in accordance with Article XVII of the By-Laws, and the following resolution was unanimously adopted:

RESOLVED, that the formation of a Division of Petroleum Technology be authorized in accordance with the By-Laws providing for the organization of Divisions.

The president appointed the present Committee on Petroleum and Gas as a committee to put this resolution into effect.

The following resolutions were unanimously adopted:

BE IT RESOLVED:

That the American Institute of Mining and Metallurgical Engineers found a bronze medal in memory of Captain Anthony F. Lucas.

That a perpetual fund adequate for this purpose be raised by popular subscription, which will be conserved and administered by the Institute.

That the medal be granted on suitable occasions for noteworthy future contributions to knowledge of oil or gas fields, or to the technology of producing oil and gas.

That the Institute be authorized to accept subscriptions for this purpose.

That the officers of the Institute be authorized to plan the best method of administering the fund and of selecting worthy recipients of the medal.

The new Petroleum Division has guaranteed to raise the required fund.

## Papers for Fall Meeting

MANUSCRIPTS of papers to be presented at the Fall Meeting of the Institute, 1922, must reach the Secretary's Office by July 1. If a paper is to be submitted through a technical committee, it should reach the chairman of that committee early enough so that he can transmit it to the Institute by the date named.

# Local Sections and Affiliations

## Local Section Convention

LOCAL sections of the Institute are a conception of rather recent date, but the seed having once taken root the growth of the idea has been rapid, and there are now 26 full-fledged sections. The first convention of these sections was called on the occasion of the annual meeting of the Institute in February last. Sixteen sections were represented by their officers or appointed delegates, and round-table conference was held on subjects that these representatives chose to bring forward.

President Dwight, who presided, opened the discussion by referring to a subject to which the directors have given much study, that is, the union of engineering societies for work of common interest. Philip N. Moore, of the St. Louis Section, said, "Your presence here marks a distinct step in a desirable object, namely, the gradual decentralization of the Institute, the turning of its councils into the hands of those who can not be here constantly."

L. W. Wallace, secretary of the Federated American Engineering Societies, told of the work that it is doing in the way of educating the public to a realization of what engineers were doing and could do toward the advancement of industry and public welfare.

The Employment Bureau, in which the Institute is an active participant, was described by Mr. Swartout, who told of the methods employed in New York for securing the attention of employers and of how these might be copied to advantage by the local sections.

President Dwight spoke of the relation of the local sections to the Institute, the need of retaining the active interest of local members, and the need of searching for men suitable for membership in the Institute and thereby strengthening the local sections.

W. E. McCourt, of the St. Louis Section, told how that section is coöperating with the Federated and how it is conducting its own small employment bureau, then, passing on to local activities, explained how the section is participating not only in matters of engineering interest but also in civic and state affairs. Two general and rather largely attended meetings are held by the section every year, with monthly meetings of less pretention in the intervals. He asked that some arrangement be developed whereby local secretaries may be kept advised of all new members and changes of address in the various districts and said, "We feel that our group exists, among other reasons, for the purpose of bringing the mining engineers into closer contact, especially bringing the younger men into contact with the older men. I spend much time at this. We have been very successful and it pays. A man feels that he has a home when he comes to our district, and that makes him a good and contented member."

Horace F. Lunt, of the Colorado Section, spoke

Digitized by Google

particularly on the close coöperation between the Denver members and the Junior Associates at the School of Mines at Golden. Members from Denver make a point of going to the monthly meetings at Golden, while the boys are encouraged to attend the meetings of the section at Denver. The members of the latter section feel that this plan is of great benefit to both the older and younger members of the Institute. Mr. McCourt said that the St. Louis Section members follow much the same practice with the students of the mining school near that city.

William Kelly, of Vulcan, Mich., had several constructive suggestions and said in part:

I conceive that the purpose of this meeting is to discuss the manner in which the local section may assist in bringing the individual member closer to the Institute. The local section centering in a city may easily gather to its meetings quite a number of members, but the time required and the expense incurred when the section covers a wide area make large meetings almost prohibitive, unless something of particular interest draws them together.

I have thought that we might secure a more direct connection between the sections and the Institute if it were possible to arrange to have the directors more representative of the sections. Just what improvements may be made in this direction, I do not know, but it is something worth thinking about.

We have recently had placed before us by the directors the matter of the registration of engineers. This is a matter of complying with state laws and if the mining engineers are going to do anything it will have to be done through local sections.

It is a political question, but one in which all engineers are interested, and if taken up by the sections I feel that it may be a means of uniting the sections a little more closely and at the same time hold us closer to the Institute.

Mr. Dwight explained to the members that this was one of the subjects he had on his list, for he, too, felt that it was one of great importance to mining engineers. The opinion among mining engineers being almost unanimous, the members of each section could strongly oppose legislation in this direction, knowing that they would have all the backing that the Institute could possibly give.

Charles B. Murray, secretary of the Ohio Section, said that in Cleveland they have been trying to have meetings every month, but he thought that perhaps this was too often. Mr. Murray felt that section members should not be called upon for any local dues and thought that the fact of their being asked to contribute to local expenses militated against large local attendance and reflected adversely on the interest of local members in the Institute. The death of the licensing bill in Ohio was largely due to the work of the local section at the last meeting of the Legislature and he promised that it would be opposed with equal force when it comes up again.

E. D. Gardner, of San Francisco, said that their section now includes nearly all eligible members of the Institute and that it is a very live section.

L. K. Armstrong, of the Columbia Section, said that they regard every man within their territory as a member of the local section and treat him as such until he becomes one in fact. Mr Armstrong continued:

We have two mining schools near us, one at Washington, the other at the University of Idaho. Our local engineers often visit these schools and we are well repaid, getting youth for ourselves while giving them of our experience.

Washington possesses great resources both in metallic and non-metallic wealth. During one of our four annual meetings we take a trip through one of the mining districts, meeting the men and getting acquainted with the industry.

In Spokane we have a club of the members of the four Founder Societies and once a week we have a dinner, the average attendance being about 40. The only difficulty with these meetings is that they are so interesting that no one ever wants to go home. This club has ventured into local politics and has been successful in securing the employment of engineering talent for our civic improvements.

We have found that the Institute spirit of exchanging information has been growing rapidly in our district. Only a few years ago it was customary for the operators in the Coeur d'Alene district to keep their work and their expenses to themselves. A most decided change has come about. Since 1915, almost every plant has been as wide open as earlier it was firmly closed. The Institute's spirit has accomplished splendid results both for the operators and the engineers of our country.

One of the most important things is to maintain friendly relations with headquarters; not always harmony perhaps, for we cannot always see eye to eye. If we are not getting what we want we go after it or learn why we cannot have it.

Arthur Thacher, of St. Louis, said, "We had, in Missouri, the same experience as Mr. Armstrong mentioned in the Coeur d'Alene. For 20 years or more after our lead mines were opened their shafts were closed to visitors. Largely through Mr. Moore, the Institute, and the St. Louis members, the reticence to publicity has been overcome and a mining engineer now goes where he lists through the mines and plants."

Mr. Dwight then took up the subject of licensing engineers, telling the members of the convention that it had come upon the mining engineers with rather startling rapidity. He told of the study given to the subject by the American Engineering Council and its attempt to draw up a model law that could be supported by all engineers. When the model law finally came before that body for adoption, opinion proved it to be about equally divided and a new attempt is now being made.

In sending out its resolution to local sections, it was not the intent of the directors to guide them in the course that they should pursue but rather to advise them that if they wish to exert their influence against the licensing of mining engineers they may know that they have the backing of a great majority of the members of the Institute.

W. Spencer Hutchinson, of Boston, spoke at length of the desire of the Boston Section to join with the Affiliated Technical Societies of Boston and asked for suggestions as to how they might secure the necessary financial assistance that such affiliation would require.

In bringing the meeting to a close, Mr. Dwight said, "I would like to take this opportunity of saying that I think this meeting has been productive of a great deal of good. It has brought into contact all parts of the country. It has been most enlightening and helpful to your new officers, who will be able to feel that they are in closer touch with the sections, and that means with the membership. We will certainly strive to carry on the good work, and serve you as efficiently and as effectively as possible."

## Annual Meeting of Montana Section

THE ninth annual meeting of the Montana Section was held at the Silver Bow Club, in Butte, on the evening of March 18. Theodore Simons, past chairman, presided, and 39 members and guests were present.

John L. Boardman read a paper on Economic Aspects of Safety First, and Rene Engel presented one on Reclamation of Exhausted Oil Fields. Brief addresses were made by Albert Burch, chairman of the San Francisco Section; W. B. Daly, member of the Montana Section; and William H. Bassett, of the American Brass Co., Waterbury, Conn.

Officers for the ensuing year were elected as follows: chairman, W. B. Daly; vice-chairman, L. V. Bender; secretary-treasurer, E. B. Young; members of executive committee, E. M. Norris and George T. McGee.

Five meetings of the Montana Section were held during 1921.

---

## Fuel Problems and Mining Policy

THE 73rd meeting of the Boston Section was held on Monday evening Feb. 6, 1922. After a dinner, which was well attended, the business meeting was called to order by Chairman W. Spencer Hutchinson, with 53 members and guests present.

By request, Charles T. Main, one of the guests gave a brief account of the efforts of the combined engineering committee last year in defeating the Engineers License Bill in Massachusetts, and called attention to the effectiveness of combined effort in matters of that kind. H. Foster Bain, director of the Bureau of Mines, was the speaker of the evening. He addressed the meeting on the Fuel Problems of New England. Mr. Bain introduced the subject by saying that in ancient times the nation or individual that owned and obtained the results of the labors of the greatest number of slaves was wealthiest but that today the fuel consumption is in a general way the best index of industrial activities. In other words, the community with the greatest number of tons of coal working for it is likely to be the one of greatest industrial importance.

Some interesting figures were given showing the fuel consumption per capita in different parts of the country, and for different periods during modern times. Mr. Bain discussed the different forms of fuel available and in use here and the geographical distribution and reserves of each. He brought out the fact that the supply of anthracite is definitely limited, and that therefore the production is not apt to increase greatly, nor the costs of mining to be materially reduced.

He pointed out also that the bituminous coal and oil resources are very large in extent, and the production is likely to increase. These have the advantage of being closer to the Atlantic seaboard, and will therefore benefit from the anticipated reductions in marine freight rates.

Mr. Bain expressed the opinion that the use of soft coal and oil would probably increase much more rapidly in New England than that of anthracite, and that the latter would probably ultimately be used only for domestic purposes.

Mr. Bain called attention to the fact that the high cost of transporting anthracite by rail is due to the immense amount of railroad equipment required, the investment on which probably exceeds the investment in equipment at the mines, and also discussed the proposal which has frequently been made to generate electric power at the mines and transmit it long distances instead of hauling the coal; he believes that little could be gained in this way, on account of the high investment cost of transmission lines.

Regarding the possibilities of hydro-electric development in New England, Mr. Bain said that, while no doubt important, they do not form a large factor, as surveys have shown that if all the hydro-electric power in New England were developed it would not greatly reduce the coal consumption.

Upon the conclusion of his talk, Mr. Bain showed a very interesting film prepared under the supervision of the Bureau of Mines, illustrating the manufacture of carborundum and other abrasive products at the plant of the Carborundum Co. in Niagara Falls.

The 74th meeting of the section was held on March 6, with 26 members and guests present. In the absence of the chairman, the meeting was called to order by Vice-chairman F. W. Paine.

At the close of the business session, Mr. Paine announced that the remainder of the meeting would be a joint technical session with the Mining and Metallurgical Society, with Allen H. Rogers, president of that society, presiding. Mr. Rogers took the chair and introduced Van H. Manning, director of the American Petroleum Institute, who was scheduled to speak on Foreign and Domestic Mining Policy.

Mr. Manning commented on the lack of a definite mining policy, especially foreign, which had characterized our Government in the past, and described the steps leading to the appointment of a committee of the Mining and Metallurgical Society to study the matter. He read the report of this committee and discussed it at considerable length, the gist of the report and his remarks being that inasmuch as the natural distribution of minerals does not conform to national boundaries, it is essential for the good of the world in general that they be moved freely from one country to another without undue tariff restrictions and that their development be permitted to anyone needing them, so far as possible without restriction as to nationality. Considerable discussion followed.

Officers for the year were elected as follows: chairman, W. Spencer Hutchinson; vice-chairman, H. A. Wentworth; secretary-treasurer, Roy B. Earling; members of executive committee, F. A. Eustis, Daniel Cushing.

Digitized by Google

## St. Louis Section Annual Meeting

THE ninth annual dinner and meeting of the St. Louis Section was held on April 1, 1922, with 54 members and guests in attendance. F. W. DeWolf presided. At the close of the dinner, the secretary reviewed the activities of the section during the past year, noting, among other things, that five meetings have been held since the last annual meeting. At the fifth one, held on March 1, Eugene McAuliffe gave a paper on the bituminous coal situation.

At the annual meeting, Colonel Dwight, president of the Institute, addressed the section on the subject of Institute activities and policies. W. E. Rolfe, vice-president of the Federated American Engineering Societies, spoke on the work of that organization, and R. G. Hall gave an illustrated talk on some of his experiences during a stay of several years in Burma.

The following were elected officers of the St Louis Section for the current year: chairman, B. O. Mahaffey, vice-chairmen, A. W. Dickinson, Charles T. Orr, C. G. Dresser; secretary-treasurer, W. E. McCourt; members of executive committee, A. H. Cronk, I. F. Hodges, J. D. Robertson, L. E. Young; F. W. DeWolf, retiring chairman.

## Metric System Discussed by Colorado Section

A MEETING of the Colorado Section was held following a 6:30 dinner at the Albany Hotel, Denver, on March 24, 1922. Chairman Hursh presided, and 62 members and guests were present. Popular songs, led by W. H. Bullock, were sung between courses.

Mr. Farish, chairman of the committee appointed to consider the revision of the mining laws, reported that the committee, consisting of himself, James Underhill and Russell Paul, had decided that the question had been fully covered by the Colorado Metal Mining Association and the American Mining Congress and that any definite report from the Colorado Section of the Institute would simply be a duplication. This report was accepted.

The committee appointed to consider the adoption of the metric system, consisting of R. J. Grant, chairman, H. B. Lowden and Herbert Addison, reported, on the basis of the questionnaire of the Mining and Metallurgical Society of America, that while the general introduction of the metric system might constitute an advance in efficiency, a general change would be accompanied by vast confusion. If adopted, the change should be left entirely to individual initiation; not be assisted by resolutions of technical and business organizations; and that the Federal Government should not take any further steps in the matter, except possibly in coöperation with Great Britain. This report was adopted.

R. I. Meeker, special deputy state engineer, gave an interesting account of the interstate controversy concerning the waters of the Colorado River, and F. W. Whiteside, chief engineer of the Victor-American Fuel Co. and president of the Rocky Mountain Coal Mining Institute, made an address on Coal, illustrated by lantern slides showing the mining and handling of coal. George Watkin Evans, a prominent coal mining engineer of Seattle, made a brief speech, and George J. Bancroft gave an account of some of the early projects for transporting water from the Colorado River basin to other watersheds.

## Mining in Mexico

THERE was a specially called meeting of the Columbia Section at the Davenport Hotel, Spokane, on March 16, to hear a lecture by Dr. Henry Mace Payne on Mining in Mexico. The meeting was preceded by a dinner party, at which 24 members, ladies and guests, were present. About 200 persons were present for the lecture.

Doctor Payne said that Americans should take a lively interest in the Mexican situation, because, with the defection of Russia and the turmoil in Europe, American investment may very logically be directed toward Mexico.

The present government is building many schools and establishing training schools for teachers. Automobile roads are being built and the railroad lines are being rapidly rehabilitated. Mining is being actively resumed in silver and the higher grade properties in lead, zinc, copper and gold are beginning to receive attention. Interest is centered in silver, however, because of the proposed subsidy on silver mining in Mexico, which would place silver there on a par with the Pitmann Act in the United States.

Doctor Payne showed lantern slides, depicting scenes of domestic, rural, city and mining activity.

## Affiliated Student Societies

**Harvard University.**—The Geological Club has been accepted as an affiliated student society of the American Institute of Mining and Metallurgical Engineers. The purpose of the club is to further the study of geology and geography at Harvard University. There are 41 active members, including graduate and undergraduate students. The officers are: James A. Noble, president; S. C. Spindel, vice-president; Gordon Gunther, secretary; R. M. Burke, treasurer; T. H. Clark, graduate representative.

**Lafayette College.**—At a meeting of the John Markle Mining Society, held in South College on March 31, Prof. D. A. Hatch delivered an address on the Present Coal-mining Situation. He told about the steady growth of the United Mine Workers' Union and gave a brief history of past strikes. He gave the demands of the miners in the present strike and some of the opinions of the public and operators.

# Correspondence and Discussion

## Northwest Mining Association on Revision

ENCLOSED herewith you will find copy of resolution adopted by the Northwest Mining Convention, in twenty-seventh annual assembly during the week of Feb. 14–18, 1922.

We commend the same to your earnest consideration.

Northwest Mining Association,
G. B. DENNIS,
*President.*

SPOKANE, WASH., Feb 7, 1922.

RESOLUTION No. 12, REVISION OF MINING LAWS

WHEREAS, there is now before Congress a bill providing for revision of the mining laws for the alleged benefit of the prospector and operator of the West, and,

WHEREAS, that measure has already been opposed by the Northwest Mining Association in a resolution and able brief, prepared by Mr. Frank A. Ross, former president of that association.

NOW, THEREFORE, BE IT RESOLVED, by the Northwest Mining Convention in 27th annual assembly, this, the 17th day of February, 1922, that it endorses every word in such resolution and brief as prepared by Mr. Ross, and adopts them both *in toto* as the expression of this convention.

AND, BE IT FURTHER RESOLVED, that, in answer to criticism of the Northwest Mining Association, in a certain eastern publication, alleging that the association has, in part, reversed itself upon the matter of revision of the mining laws, this convention cheerfully admits such reversal of opinion, in part, and further declares that the mining industry of the West is tired of regulation and restriction and prefers, for the present, to work its way back to prosperity through the aid of laws which are now well understood, even though imperfect, rather than fly to evils of which it can have no knowledge short of actual operation.

AND, BE IT FURTHER RESOLVED, that this Convention extends its sincere thanks to the Northwest Mining Association for so clearly expressing its views upon this question and promises it undivided support in any further opposition to such measures that it may decide necessary.

AND, BE IT FURTHER RESOLVED, that copies of this resolution be sent to the Editor, MINING AND METALLURGY, and members of congressional delegations from Oregon, Washington, Idaho, and Montana.

SIDNEY NORMAN,
*Chairman Resolutions Committee.*

# Government Action of Interest to Engineers

## Extracts from Weekly Bulletin Issued by American Engineering Council

APRIL 14, 1922

**Trade Associations Conference.**—At a Trade Associations Conference held at the Department of Commerce on April 12, representatives of a large number of trade associations expressed their views as to proper activities which such organizations might conduct. Mr. Hoover pointed out the great progress that has been made as a result of plans to use the coöperation of technical and commercial organizations, but he emphasized especially the fact that he did not in any case desire to make such coöperation compulsory.

**Trade Associations to be Investigated and Defined.**—The Senate Commerce Committee has favorably reported a bill creating a Joint Congressional Committee to investigate and prepare legislation defining trade associations and their rights under the law. This bill failed to pass by unanimous consent April 12, but will be further pushed.

**Hydroelectric Power Projects Discussed by Cabinet.**—The Boston to Washington super-power survey, the Colorado River development and other projects were discussed by President Harding and his Cabinet on April 8, as a means of minimizing the effect of coal strikes in the future and also in relation to the general economic fabric of the country.

**Muscle Shoals Proposition.**—The chairman of the Senate Agricultural Commission will shortly propose a resolution for a government owned and operated

Digitized by Google

corporation for the development of the nitrate and water power projects at Muscle Shoals.

APRIL 7, 1922

**Patent Law, Working Clause Amendment.**—The Senate Committee on Patents held a hearing April 6 on S. 3325 which proposes to amend the patent laws so that every patent granted by the Government will have to be worked or become invalid. The Patents Committee of the American Engineering Council submitted a statement to the Senate Committee opposing a favorable report on this bill.

**Highway Legislation.**—The Committee on Roads of the House of Representatives on April 6 reported out a highway bill appropriating $65,000,000 for Federal aid during the next fiscal year and $75,000,000 for the fiscal year ending June 30, 1924.

MARCH 30, 1922

**Alaska Coal Mines.**—The Department of the Interior has taken over the work heretofore done by the Navy Department in developing coal mines in Alaska. The Secretary of the Interior has announced that Director Bain of the Bureau of Mines will go to Alaska to formulate plans for proving the extent and value of Alaskan coal mines.

## Large High-tension Electrical Transmission Systems

A COMPLETE report of the papers presented at the international conference organized by the Union des Syndicats de l'Électricité, and held in Paris, Nov. 21–26, 1921, is being prepared, and will be published in both French and English. The object of the conference was the study of technical questions relating to the construction and operation of long transmission lines operating at very high tensions.

The Union des Syndicats de l'Électricité asks those who wish this report to send word as soon as possible regarding the number of copies desired, stating which edition will be wanted, French or English. Until May 15, 1922, the price will be 60 fr. per volume; after that date, it will be about 75 fr. per volume, but cannot be fixed definitely until the number of copies to be printed has been decided. Address M. Tribot-Laspière, Secrétaire Général de l'Union des Syndicats de l'Électricité, 25 Boulevard Malesherbes, Paris, France.

## Coming Meetings of Societies

| Organization | Place | Date |
|---|---|---|
| Amer. Zinc Inst. | St. Louis, Mo. | May 8–9 |
| Amer. Soc. Mech. Engrs. | Atlanta, Ga. | May 8–11 |
| Foreign Trade Convention | Philadelphia, Pa. | May 10–12 |
| Amer. Foundrymen's Assn. | Rochester, N. Y. | June 5–9 |
| Inst. of Metals Div. A. I. M. E. | Rochester, N. Y. | June 5–9 |
| Soc. Automotive Engrs. | White Sulphur Spr., W. Va. | June 20–24 |
| Amer. Assn. for Adv. of Sci. | Salt Lake City, Utah | June 22–24 |
| Amer. Soc. for Test. Mats. | Atlantic City, N. J. | June 26–July 1 |
| International Chemical Conference | Lyons, France | June 27–July 2 |
| Assn. des Ingénieurs sortis de l'Ecole de Liége | Liége, Belgium | June 11–16 |
| Congress on Industrial Chemistry | Marseilles, France | July 2–7 |
| 13th Intl. Geol. Congress | Brussels, Belgium | Aug. 10–19 |

# Increase of Membership Department

**Total membership as of April 15, 1922, is 10,152**

APPLICATIONS FOR MEMBERSHIP.—The Institute desires to extend its privileges to every person to whom it can be of service. On the other hand, it is not desirable that persons should be admitted to membership in classes for which they are not qualified. Members of the Institute can be of great service if they will make a practice of glancing through the list of applicants and promptly notifying the Committee on Membership, or the Secretary of the Institute, of any person whom they think should not be classified in accordance with the list given.

The following persons have been proposed during the period March 20, to April 19, 1922, for election as members of the Institute. Their names are published for the information of Members and Associates, from whom the Committee on Membership earnestly invites confidential communications, favorable or unfavorable, concerning these candidates. A sufficient period (varying in the discretion of the Committee, according to the residence of the candidate) will be allowed for the reception of such communications, before any action upon these names by the Committee. After the lapse of this period, the Committee will recommend action by the Board of Directors, which has the power of final election.

## Candidates for Membership

### Members

**1—Alfred Paul Frey,** Cartagena, Colombia, S. A.
Present position—1921 to date: Geologist, Bataafsche Petroleum Maaschappij, Cartagena.
Proposers: W. H. Whittier, W. Van Holst Pellekan, George A. Macready.

**2—Julian Stuart Gravely,** New Haven, Conn.
Present position—1920 to date: Engineering Superintendent, Winchester Repeating Arms Co.
Proposers: William B. Price, W. M. Corse, Paul D. Merica.

**3—Robert Keffer,** Anaconda, Mont.
Present position—1919 to date: Research Chemist, Anaconda Copper Mining Co.
Proposers: Louis V. Bender, Frederick F. Frick, Harry S. Ware.

**4—Karl Hartness Marsh,** Sydney, Nova Scotia, Canada.
Present position—1920 to date: Chief Engineer, Dominion Iron and Steel Co. and Dominion Coal Co.
Proposers: Walter Herd, A. W. MacDonald, F. E. Lucas.

**5—Charles Harold Memory, Jr.,** South Orange, N. J.
Present position—1919 to date: Coal Mining Department, American Smelting and Refining Co.
Proposers: C. A. Baker, C. E. Meissner, H. A. Guess.

**6—James Isaac Moore, Jr.,** Britannia Beach, B. C., Canada.
Present position: Mine Superintendent, Britannia Mine.
Proposers: J. F. Kemp, Robert Peele, J. Pendleton Wood.

**7—Gus Lewis Rogers,** Homestead, Ore.
Present position: Secretary and General Manager, Panhandle Copper Co.
Proposers: Robert M. Betts, James A. Panting, Eugene Antz.

**8—Robert Pierce Sanborn,** East Orange, N. J.
Present position—1920 to date: Manager, Traction Department Edison Storage Battery Co.
Proposers: John T. Ryan, George H. Deike, Howard Eckfeldt, A. C. Callen, William H. Patton.

**9—Dale Raymond Snow,** Tulsa, Okla.
Present position—1920 to date: Chief Geologist, Waite Phillips, Oil and Gas Producer.
Proposers: H. B. Goodrich, M. M. Valerius, C. A. Cheney.

**10—William Nelson Watson,** Broken Hill, N. W. Rhodesia, Africa.
Present position—1921 to date: Research Chemist, Rhodesia Broken Hill Development Co.
Proposers: J. O. Betterton, Virgil T. Price, S. J. Splak.

**11—Arthur Sampson White,** Dowell, Jackson Co., Ill.
Present position—1921 to date: Mining Engineer, Union Colliery Company, St. Louis, Mo. (Mine at Dowell, Ill.)
Proposers: Eugene McAuliffe, Arthur Thacher, Philip N. Moore.

### Associates

**12—Nicholas Nikolaevitch Vishnevsky,** Washington, D. C.
Present position: U. S. Bureau of Mines, Salt Lake City, Utah.
Proposers: Robert Peele, R. M. Raymond, Edward F. Kern.

### Junior Associates

**13—E. Maurice Adams,** Moorhead, Minn.
Student, University of Minnesota.
Proposers: W. R. Appleby, Peter Christianson, Walter H. Parker.

**14—Harry John Bruner,** Boston, Mass.
Student, Massachusetts Institute of Technology.
Proposers: Edward E. Bugbee, Charles E. Locke, Carle R. Hayward.

**15—Donald Barcher Campbell,** Corvallis, Ore.
Student, Oregon State College.
Proposers: J. H. Batcheller, Charles E. Newton, G. E. Stowell.

**16—Clarence Lewis Christiansen,** Portland, Ore.
Student, Oregon Agricultural College.
Proposers: James H. Batcheller, Charles E. Newton, G. E. Stowell.

**17—Gus Edward Danielson,** Cambridge, Mass.
Student, Massachusetts Institute of Technology.
Proposers: Edward E. Bugbee, Charles E. Locke, Carle R. Hayward.

**18—Jerome Thomas Eckenrode,** Steelton, Pa.
Student, Pennsylvania State College.
Proposers: D. F. McFarland, A. M. Rodgers, William R Chedsey.

**19—John Carton Flaherty,** Boston, Mass.
Student, Massachusetts Institute of Technology.
Proposers: Edward E. Bugbee, Charles E. Locke, Carle R. Hayward.

**20—Warren Roy Gettler,** Hannibal, Mo.
Student, Missouri School of Mines.
Proposers: Charles Y. Clayton, T. M. Bains, Jr., M. H. Thornberry.

**21—Arnold A. Gustafson,** Duluth, Minn.
Student, University of Minnesota.
Proposers: W. R. Appleby, Peter Christianson, Walter H. Parker.

**22—Edwin James Heap,** Atlantic, Mass.
Student, Massachusetts Institute of Technology.
Proposers: Edward E. Bugbee, Charles E. Locke, Carle R. Hayward.

**23—Lawrence Irving Hope,** Minneapolis, Minn.
Student, University of Minnesota.
Proposers: W. R. Appleby, Peter Christianson, Walter H. Parker.

**24—Elmer Lawrence Johansen,** Somerville, Mass.
Student, Massachusetts Institute of Technology.
Proposers: Charles E. Locke, Carle R. Hayward, W. Lindgren.

**25—Fitzhugh Bayton Jones,** Golden, Colo.
Student, Colorado School of Mines.
Proposed by: R. J. Grant, James Underhill, J. C. Roberts.

**26—Dewey Bernard Larson,** Corvallis, Ore.
Student, Oregon School of Mines.
Proposers: Charles E. Newton, J. H. Batcheller, G. E. Stowell.

**27—Wade Vernon Lewis,** Corvallis, Ore.
Student, Oregon School of Mines.
Proposers: James H. Batcheller, Charles E. Newton, G. E. Stowell.

**28—Frank Cornelius Linton,** Corvallis, Ore.
Student, Oregon School of Mines.
Proposers: J. H. Batcheller, Charles E. Newton, G. E. Stowell.

**29—Curtis Gilliam Mohney,** Corvallis, Ore.
Student, Oregon School of Mines.
Proposers: James H. Batcheller, Charles E. Newton, G. E. Stowell.

**30—Paul Fisher Mumma,** Bethlehem, Pa.
Student, Lehigh University.
Proposers: Benjamin L. Miller, Howard Eckfeldt, G. A. Roush.

**31—Richard Charles Patten,** Minneapolis, Minn.
Student, University of Minnesota.
Proposers: W. H. Emmons, Clinton R. Stauffer, Walter H. Parker.

**32—Frank James Plut,** Grosby, Minn.
Student, Minnesota School of Mines.
Proposers: E. H. Comstock, Peter Christianson, Walter H. Parker.

**33—Darwin Jesse Pope,** New York, N. Y.
Student, Columbia University School of Mines.
Proposers: R. M. Raymond, Robert Peele, Arthur L. Walker.

**34—Palmer Cosslett Putnam,** Cambridge, Mass.
Student, Massachusetts Institute of Technology.
Proposers: Edward E. Bugbee, Charles E. Locke, Carle R. Hayward.

**35—Horace Dwight Scruby,** Chillicothe, Mo.
Missouri School of Mines.
Proposers: C. R. Forbes, J. R. Guiteras, C. L. Dake.

**36—Alfred Richmond Smith,** Brooklyn, N. Y.
Student, Columbia School of Mines.
Proposers: R. M. Raymond, Robert Peele, Arthur L. Walker.

**37—William Wesly Staley,** Socorro, N. M.
Student, New Mexico State School of Mines.
Proposers: T. W. Quayle, W. G. Ramlow, E. H. Wells.

**38—Philip Morris Stearns,** Wakefield, Mass.
Student, Massachusetts Institute of Technology.
Proposers: Edward E. Bugbee, Charles E. Locke, Carle R. Hayward.

**39—John Wadsworth William Sullivan,** Boston, Mass.
Student, Massachusetts Institute of Technology.
Proposers: Edward E. Bugbee, Charles E. Locke, Carle R. Hayward.

Digitized by Google

**40—Parker Davies Trask,** Oakland, Cal.
Student, University of California.
Proposers: Frank H. Probert, W. S. Morley, Lester C. Uren.

**41—Louis Harold Tucker,** Lawrence, Kans.
Student, University of Kansas.
Proposers: C. M. Young, R. S. Knappen, Sherwin V. Kelly.

**42—Robert T. Wood,** Palmerton, Pa.
Student, Lehigh University.
Proposers: Benjamin L. Miller, H. B. Pulsifer, G. A. Roush.

Change of Status—Associate to Member

**43—Burnham E. Field,** Long Island City, N. Y.
Present position—1921 to date: Metallurgical Engineer, Union Carbide and Carbon Research Laboratories, Inc.
Proposers: C. E. McQuigg, A. L. Meyer, F. M. Becket.

**44—Be Van Presley,** Latouche, Alaska.
Present position—1919 to date: Mill Foreman, Kennecott Copper Corpn.

**45—Curt Nicolaus Schuette,** San Francisco, Cal.
Present position: Unemployed.
Proposers: Frank H. Probert, Byron O. Pickard, L. H. Duschak.

**46—Earl Adam Trager,** Panuco, Ver., Mexico.
Present position—1921 to date: Chief of Sub-Surface Geology, Marland Oil Company of Mexico.
Proposers: Albert D. Brokaw, W. E. Wrather, George C. Matson.

Change of Status—Junior Associate to Member

**47—Joseph C. Barton,** Ashland, Ala.
Present position—1920 to date: General Manager and Treasurer, Griesemer Graphite Co.
Proposers: K. K. Hood, Rush M. Hess, H. A. Coy, Frank C. Hooper.

**48—Henry S. Burnholz,** New York, N. Y.
Present position: Teaching temporarily.
Proposers: R. M. Raymond, Frank J. Nagel.

**49—Thomas Fraser,** Urbana, Ill.
Present position—1919 to date: Assistant Mining Engineer, U. S. Bureau of Mines.
Proposers: J. J. Rutledge, H. H. Stoek, Ray W. Arms.

**50—Herbert Betts Wolcott,** El Paso, Tex.
Present position—Manufacturer's Agent.
Proposers: John I. Kane, W. N. Small, D. Cole.

Change of Status—Junior Associate to Associate

**51—Charles Winegar Crispell,** Bridgeport, Conn.
Present position—1919 to date: Process Engineer, Bridgeport Brass Co.
Proposers: Walter R. Clark, W. R. Webster, Carl F. Dietz.

**52—Maynard Mizel,** Brooklyn, N. Y.
Present position—1921 to date: Charge of Sales Department, Phinotas Chemical Co.
Proposers: Howard Eckfeldt, Benjamin L. Miller, G. A. Roush.

**53—Edward Tuttle Plumb,** Winchester, Ky.
Present position: Statistician.
Proposers: Luther W. Bahney, F. M. Towl.

**54—Thomas Graham Ralph,** Port Huron, Mich.
Present position—1920 to date: Plant Engineer, Athol Manufacturing Co., Marysville, Mich.
Proposers: Benjamin L. Miller, Howard Eckfeldt.

**55—Raymond Samuel Weimer,** Rock Springs, Wyo.
Present position—1920 to date: Resident Mine Engineer, Central Coal and Coke Co.
Proposers: Charles H. Fulton, H. A. Buehler.

# Engineering Societies Library

HARRISON W. CRAVER, Director

The Engineering Societies Library, on the 13th floor of the Engineering Societies Building, 29 West 39th St., New York, contains approximately 150,000 volumes of engineering literature. It is open on week days, excepting holidays, from 9 a.m. to 10 p.m.

The Library offers, upon payment for the extra work required, to supply photoprints or translations of articles, make searches for information, prepare lists of references and suggest books on engineering subjects. The cost of searching is $2 an hour. Translations cost $6 and upwards per thousand words. Typewritten copies, $1 a thousand words. Photoprints, 11 by 14 in., cost $0.25.

In cases where the Library contains two copies of a book, one may be borrowed by any member. Transportation costs must be paid by the borrower.

The Library is at the service of every member. Those who cannot visit it may order searches, translations, copies, etc., by mail.

Address correspondence to the Director, Harrison W. Craver, 29 West 39th St., New York.

## Book Review

**Wealth and Income of the American People.** By Walter Renton Ingalls. York, Pa., G. H. Merlin Co., 1922. 321 pp., 6 × 9 in., cloth, $4.

The author of this book needs no introduction to the mining and metallurgical profession, either as an engineer or as an economist. His economic writings have been widely published and commented on, but this is his first book on this subject.

Wealth and Income of the American People is, as the jacket says, a survey of the economic consequences of the war. The author's aim is to inspire others to examine with greater care many of the subjects treated so they may arrive at a fuller understanding of conditions as they exist today in our economic, financial and social structure. With this end in view, the author has examined critically the European situation from an economic standpoint and has analyzed the various foreign debts to the United States, not only as to amounts but as to the likelihood and desirability and consequent effect of the cancelling of those debts by the United States. The Russian situation receives particular attention. Foreign investments of American capital in all parts of the world as well as its loans to the Allies are carefully analyzed.

The middle third of the book is taken up with a discussion of statistics, the compilation of which represents much assiduous industry on the part of the author. He has woven them into the text in such an interesting manner that one is beguiled into subsequently reading the tables. The copious references to and quotations from authoritative economic works indicate the wide study of the author and the authoritative figures received by him from living persons well known in finance and industry add to the book a human interest which does not ordinarily attach to economic dissertations.

One of the most interesting sections of the book is devoted to an evaluation of the mines and metallurgical works of the United States, part of the calculations included having been published in MINING AND METALLURGY in October, 1921. Similar studies are made of all of the major factors in the wealth of the United States, of which only a few are mentioned here to show the scope of the list; gold and silver, farms, urban real estate, farming implements, live stock, railways steam and electric, express companies, pullman cars, telephones and telegraphs, tent cars, pipe lines and petroleum tankage, light power plants, automobiles, canals, etc., etc.

Most of the comforting fallacies of the war are exploded by the author. The war did not increase the efficiency of labor but, on the contrary, labor became more inefficient, more slack, and unions enforced rules entailing not only waste of time but of labor. "Throughout this period we fatuously fondled the illusion that we were becoming very rich, contemplating that the national income, expressed in dollars, was growing fabulously, attaining the huge total of sixty-six billion dollars in 1919. . . . We deluded ourselves with the agreeable fantasy that we could have as many automobiles as we wanted; but in reality we were living on our fat using up our principal, etc. . . . The cost of living did not outrun wages. Actually the result was the other way around."

In his summary the author says, "This thesis is primarily the showing that the world became enormously impoverished by the war, and that although the United States suffered less than any other country that was engaged, its position did not escape impairment. Consequently the people of the world are confronted with the prospect of a lower scale of living, which will be the case even in the United States. . . . . Things cannot be otherwise, for any idea that the people of the world could have bettered themselves by the destruction of wealth and the loss of man power by warfare is preposterous."

One of the grave dangers of the present time is pointed out to be the attitude of the owners of surplus plant in keeping it "partially in use with the hope of getting something out of it, maintaining the deplorable conditions of an industry with an aggravated and unnecessary overhead and part-time employment of its workers." He maintains that there must be faced the writing off of plant for the reason of its uselessness, either by virtue of superfluity or obsolescence. "At the present time American mining and manufacturing industry is immensely overbuilt. Among the major industries there are but few exceptions to this. The textile industry and anthracite coal mining are in the best positions, neither of these having any abnormal surplus of capacity. Next in order are electrical manufacturing and petroleum refining, which although largely extended during the last 5 years have been so with the sound justification of especially increased demand for their products. Pigment production (white lead and zinc oxide) is also in fairly good position. Among most of the other industries overbuilding ranges from 50 to 200 per cent. This includes copper production, zinc production, iron and steel, bituminous coal, heavy chemicals (sulfuric acid and caustic soda), boot and shoe manufacturing, clothing making, shipbuilding and automobile manufacturing. The last two are in the worst way. The uselessness of most of our shipyards is already commonly recognized."

On the subject of labor unions, the writer even foresees their dissolution. He says, "Hired labor has not yet had much readjustment in wage scales, its opposition to reduction in rates having resulted in extensive unemployment, owing to the inability of industries to pay the old scales. This spells, of course, curtailment of the national income. In a former paper I indicated the probability of just such a situation and pointed out how it would lead to dissension between the agricultural workers and the town workers, which has already happened; and how furthermore it would produce a rift between organized and unorganized labor; and how eventually it would lead to a dis

Digitized by Google

ruption of the general federations of labor unions. I may go even further and foresee the waxing of the general principle of the open shop along with the waning of labor unionism."

"Labor is not going to continue to hold the mastery of the situation, in spite of declarations to that effect, but is going to lose most, if not all, of what it gained during the war and may fall to a lower scale of living than before the war. It may be that labor will lose even the 8-hour day under the economic compulsion of working more in order to meet the competition of pauperized Europe."

At dinner recently, a companion said to me, "Isn't it remarkable how Ingalls' predictions have been coming true?" Some of the factors in the present coal strike situation seem to be in a fair way of bearing out other of his forecasts.

The book is as calmly logical as a textbook but as interesting as a novel and leaves the reader with the conviction that the situations, although much worse than realized commonly, may yet be worked out if a fuller understanding of economic conditions is arrived at, governmental palliatives spurned, and common sense applied to the inexorable fundamental laws of economics.

P. E. B.

## Book Notices

**Blue Printing and Modern Plan Copying.** By B. J. Hall. London and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. 130 pp., illus., 5 × 8 in., cloth, $2.

Of interest to engineers who have plans to be copied, to installers of copying plants and to operators. The first section of the book discusses the capabilities of contact photography and allied processes for copying drawings, as well as the proper preparation of drawings for reproduction. Section two describes the machinery and apparatus used in blue-printing plants. The concluding section deals with the layout of blue-printing rooms and methods of working. Both contact and camera processes are included.

**Comprehensive Treatise on Inorganic and Theoretical Chemistry.** By J. W. Mellor. Vol. 1–2. London and N. Y., Longmans, Green and Co., 1922. 2 v., illus., 6 × 10 in., cloth, $20 a vol.

Volume one is mainly introductory. It treats of the evolution and methodology of chemistry, of chemical combination, atoms, molecules, and hydrogen and oxygen and their compounds. The second volume includes the halogens, the alkali metals and the ammonium compounds.

Subjects are treated with great fullness. Authorities are given for all statements of fact. The references to original publications are very complete. No work of similar character and completeness exists in the English language.

**Course in Electrical Engineering.** Vol. 2. Alternating Currents. By Chester L. Dawes. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1922. (Electrical Engineering texts.) 526 pp., illus., 6 × 8 in., cloth, $4.

An elementary textbook, intended as an introduction to more advanced books. For students who have such knowledge of direct currents as is given by volume one of this work, but have had no previous study of alternating currents.

**Distribution of Gas.** By Walter Hole. Fourth edition. London, Benn Brothers, Limited, 1921. 699 pp., illus., diagrs., 7 × 10 in., cloth, 50 s.

Uniform in size with Meade's "Modern Gas-works Practice," to which it forms a fitting companion. That work treats of gas manufacture, this takes up the account at the gasholder and discusses the distribution to the consumers' appliances.

The opening chapter discusses the rights and duties of gas undertakings. Succeeding chapters treat of discharges from pipes, station governors, districting, pipes and joints of iron and steel, mainlaying, valves and cocks, conduits, service pipes, meters, internal fitting, internal lighting, gas stoves and heaters, gas engines, industrial uses of gas, pressures, complaints and repairs, street lighting, high-pressure distribution, high-pressure lighting and heating, leakage, electrolysis and fusion. The information given is thoroughly representative of current practice. Obsolete matter was deleted in preparing this new edition and much that is new was added.

**Dynamic and Static Balancing.** By Edward K. Hammond. First edition. N. Y., Industrial Press; Lond., Machinery Publishing Co., Ltd., 1921. 58 pp., illus., 6 × 8 in., paper. $0.50.

A discussion of the principles of balancing, with a description of machines and methods, written in simple language. Intended for shop men. Avoids mathematical theory.

**Essentials in the Theory of Framed Structures.** By Charles A. Ellis. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1922. 330 pp., tables, 6 × 9 in., cloth, $3.50.

Contains no new principles, but sets forth the fundamental ideas in very different way from that usually adopted in textbooks. Proceed from particular cases to general ones. Each principle is introduced by illustrative numerical problems, through the study of which the student is led to develop the general expression. The book requires little use of the calculus.

**Giesserei-Handbuch.** Herausgegeben vom Verein Deutscher Eisengiessereien Giessereiverband in Düsseldorf. München, R. Oldenbourg, 1922. 264 pp., tables, 7 × 10 in., cloth, 300 M.

Prepared by the German Ironfounders' Association as a convenient compendium of data used by foundry men. Includes the standards adopted by many European railroads, associations and societies, methods for the analysis of cast iron, coal, coke, slags and flue gases, physical data for iron and other materials, the German standards for cast-iron pipe, tariff and statistical data concerning the trade, trade associations, and directors of German foundries and foundry supply dealers.

**Heating and Ventilation.** By John R. Allen and J. H. Walker. Second edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1922. 332 pp., illus., diagrs., tables, 6 × 9 in., cloth, $3.50.

A textbook for use in engineering and architectural schools, also for use as a handbook by engineers and architects. The text has been thoroughly revised and enlarged to include recent developments

**Hydraulics of Pipe Lines.** By W. F. Durand. N. Y., D. Van Nostrand Co., 1921. (Glasgow text books.) 271 pp., diagrs., 6 × 9 in., cloth. $4.50.

Intended to give a discussion, in engineering form, of the more important hydraulic problems which arise in connection with pipe lines and pipe line flow. No attempt is made to treat the subject structurally or descriptively. The successive chapters discuss general hydraulic principles, surge, water ram or shock, stresses in pipe lines, materials, construction, design, and oil pipe lines.

**Introduction to Physical Chemistry.** By Sir James Walker. Ninth edition. Lond., Macmillan and Co., Ltd., 1922. 438 pp., illus., 6 × 9 in., cloth, $4.50. (Gift of the Macmillan Co., N. Y.)

Intended for the student with some knowledge of chemistry and physics who wishes a work that will effect a connection between the knowledge he possesses and the works on physical chemistry.

**Ions, Electrons, and Ionizing Radiations.** By James Arnold Crowther. Third edition. N. Y., Longmans, Green & Co., Lond., Edward Arnold, 1922. 292 pp., diagrs., 6 × 9 in., cloth. $4.

This edition includes the results of recent work on constants, a fuller account of positive rays, and an account of the nuclear theory of the atom. The book is intended to be a reasonably complete account of the present state of the subject, suitable for students who wish a systematic knowledge of the late developments in physics.

**Mathematical Philosophy.** By Cassius J. Keyser. N. Y., E. P. Dutton & Co., 1922. 466 pp., 6 × 8 in., cloth, $4.70.

A course of lectures by the Adrian Professor of Mathematics at Columbia University. The author attempts to give an insight into the essential nature of mathematics regarded as a distinctive type of thought, to show what is characteristic and fundamental in mathematical method, acquaint readers with the great mathematical concepts that are available to laymen, and thus to give an understanding of mathematics in relation to the other sciences and arts.

**Modern Tunneling.** By David W. Brunton and John A. Davis. New Chapters on Railroad Tunneling by J. Vipond Davies. Second edition. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1922. 612 pp., illus., 6 × 9 in., cloth, $6.50.

Digitized by Google

Apparently a reprint of the first edition, published in 1914, with the addition of five chapters, comprising 157 pages, written by Mr. Davies. The original book contained data on American tunneling methods and equipment, but was restricted to tunnels of small size in which the heading was excavated at a single operation. The new matter deals with large tunnels for railroads and highways, both subterranean and subaqueous. Extensive bibliographies are included.

**Petroleum.** By Sir Boverton Redwood. Fourth edition. Lond., Charles Griffin & Co., Ltd.; Phila., J. B. Lippincott Co., 1922. 3 vol., maps, plates, illus., tables, 6 × 9 in., cloth, $39.

Sir Boverton Redwood's classic work is the product of a long professional career as a petroleum technologist. The material collected, after being critically sifted in the light of his broad experience, resulted in a book that for 25 years has been recognised as an authoritative reference work.

The present edition was in preparation when the author died in 1919, and certain parts had received his final revision. The remainder has been revised by his friends, and the work has been seen through the press by A. W. Eastlake and Robert Redwood.

Commencing with a historical account of the industry, the distribution, physical and chemical properties, and origin of petroleum are discussed in volume one. Volume two is devoted to production, refining, transportation, storage and distribution, and to the shale oil industry. Volume three treats of testing, uses, and laws; it also contains statistics, import duties and an extensive bibliography. This contains nearly nine thousand references; but seems to include few, if any, publications later than 1911.

**Practical Chemistry of Coal and Its Products.** By A. E. Findley and R. Wigginton. London, Benn Brothers, Limited, 1921. 144 pp.,-diagrs., tables, 6 × 9 in., cloth. 12 s. 6 d.

A collection of reliable methods for analysing coal, coke, ammonia liquor, benzene, coal tar, water, gas, and similar products and raw materials of the gas and coke industries. Based on the course in fuel technology at Sheffield University.

**Probenahme und Analyse von Eisen und Stahl.** By O. Bauer and E. Deiss. Zweite auflage. Berlin, Julius Springer, 1922. 304 pp., illus., 7 × 10 in., cloth, 472 M.

Presents methods for sampling and analysing iron and steel adopted by the authors for their work at the National Testing Laboratory in Berlin. The first section, by Prof. Bauer, discusses sampling, emphasizes the importance of proper sampling and gives much information upon proper methods of taking, polishing and etching samples for microscopic examination. The metallographic characteristics of the constituents of iron and steel are described and directions given for securing representative samples of iron and steel for examination. The second section, by Prof. Deiss, gives reliable methods for the accurate chemical determination of the various constituents of iron and steel.

**Questions and Answers Relating to Diesel, Semi-Diesel and Other Internal-combustion Engines, Air Compressors,** etc. By John Lamb. Lond., Charles Griffin & Co., Inc.; Phila., J. B. Lippincott Co., 1922. 209 pp., 4 × 5 in., cloth. 5 s.

A small pocketbook of practical information for steam engineers and others preparing for license examinations.

**Real Mathematics.** By Ernest G. Beck. Lond., Henry Frowde and Hodder & Stoughton, 1922. (Oxford technical publications.) 306 pp., diagrs., 5 × 8 in., cloth, 15 s. (Gift of Oxford University Press, American Branch.)

This book is intended to assist in the acquisition of a real, serviceable, sound mathematical equipment, by augmenting standard textbooks and orthodox methods of study. The author hopes it will contribute toward the adoption of a change of attitude toward mathematics by those who require it as a part of their working equipment, by showing it as an actual, tangible reality, instead of a collection of rigid and unrelated rules and formulas. The method given assists the student to visualize the various operations and processes used in mathematical calculation.

**Textbook of Fire Assaying.** By Edward E. Bugbee. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1922. 254 pp., illus., 6 × 9 in., cloth.

Based on the course at the Massachusetts Institute of Technology and intended as a college textbook; but will also be useful to more mature students. An endeavor has been made to give the scientific reasons underlying the phenomena that occur and the rationale of the processes and manipulations.

**Textbook of Mineralogy.** By Edward Salisbury Dana. Third edition, revised and enlarged by W. E. Ford. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1922. 720 pp., illus., 6 × 9 in., cloth, $5.

It is 24 years since the second edition of this work appeared. The changes involved in the present edition are chiefly those of addition, the general character and form of the book remaining unchanged. The methods employed in the use of the stereographic and gnomonic projections have been introduced into the section on Crystallography. The section on the Optical Characters of Minerals has been rewritten. All new species have been briefly mentioned in their proper places in the section on Descriptive Mineralogy.

**Zirconium and Its Compounds.** By Francis P. Venable. N. Y., Chemical Catalog Co., Inc., 1922. (American Chemical Society Monograph series.) 173 pp., 6 × 9 in., cloth, $2.50.

A concise account of present knowledge of the chemistry of zirconium and its compounds with other elements. Methods for the analysis of zirconium compounds, and chapters on technical applications and patents are included. An extensive bibliography is given.

# Employment Service Bureau

Notices for this column are not acknowledged by letter. Notices received before the 15th of the month will appear in the next issue.

Correspondence relating to replies to advertisements returned to the Employment Bureau will be held in the Bureau one month.

Positions of the Bureau are on file in the offices of the member societies of the Federated American Engineering Societies and with secretaries of A. I. M. E. local sections.

## Engineers Available

**Geologist** with superior training and recognized professional standing, who had had ten years successful experience in scientific investigations and practical economic work in oil, coal, and mineral deposits, desires position as chief of geological department of reliable company or institution. IM-1574.

**Metallurgical Engineer.**—School of Mines graduate. Has done practically every thing around mine, mill, copper and lead smelters, up to superintendent of large works. Experienced in leaching and volatilization methods. Can help solve difficult ore-treatment problems. Good organizer, and can handle both American and Mexican labor successfully. Age 35. Married. IM-1575.

**Metallurgical Engineer.**—Graduate. Experience as chief chemist, cyanide-mill superintendent, flotation superintendent, construction engineer, production engineer and in iron blast-furnace operation. Age, 33. Minimum salary $300 per month in United States. For foreign work, $500 per month. IM-1576.

**Superintendent.**—Twelve years' experience Ohio and West Virginia coal mines, examination, surveys, construction and operation. Married. Age 36. IM-1577.

Digitized by Google

**Mining Engineer.**—Design and construction of coal tipples, power plants and general machinery. Surveying, mapping and general coal-mine development. Experienced draftsman in all work. IM–1578.

**Quarry and Open-cut Operator.**—Has made specialty of surface mining of large orebodies, big tonnages and low unit costs. College man, age 39, married. Eight years in the United States and seven in Mexico, in gold, silver-lead and copper properties, underground, surface operations, construction, efficiency and cost analysis. Speaks Spanish fluently. IM–1579.

**Mining Geologist.**—Harvard graduate. Five years experience, petroleum and mining geology in United States and Africa. Accustomed to handling prospecting operations. Thoroughly acquainted with diamond drilling. Wishes position leading to responsible executive in directing mine development. IM–1580.

**Mining Engineer** wants summer work. College and technical graduate. At present instructor in mining, having had five years experience in practical underground, efficiency, valuation, operating, and educational mining work. Age 33. IM–1581.

**Chemical Engineer.**—Seven years as production superintendent in Chile. Experienced in leaching ore, treatment of slimes, filtration, etc. Thoroughly familiar with Spanish. Wants opportunity for advancement. IM–1582.

**Mining or Manufacturing.**—Technical graduate at present engaged in factory management control—3 years engineering and manufacturing experience—invites offer for position as sales engineer, secretary or assisiant to executive who is a developer of ambitious men. Age, 26. Unmarried. IM–1583.

**Manager or Superintendent.**—Graduate. Seventeen years experience, development and operation of mining properties. Ten years with present company in Mexico. Speaks Spanish. IM–1584.

**Chemical and Electrochemical Engineer.**—Experienced in production of phosphoric acid from natural phosphate rock, both by sulfuric acid decomposition and electric furnace volatilization methods; also in manufacture of various phosphate compounds. Age 34. Married. IM–1585.

**Junior Engineer.**—Available June 15 after graduation from M. I. T. Two years experience in mining and engineering. IM–1586.

## Positions Open

**Instructors.**—Engineers willing to consider teaching positions are invited to register with the Employment Service, which has been called on to fill positions varying in grade from laboratory assistant to heads of departments in various engineering and technical schools of this country. Blanks for registration and information regarding the Bureau may be obtained from Walter V. Brown, Manager Employment Service, 29 West 39th St., New York City.

**Draftsmen.**—Mining engineers qualified to fill structural and architectural drafting positions will please apply at once to Walter V. Brown, Manager Employment Service, 29 West 39th St., New York City.

**Mine Foreman.**—Bituminous-coal mining experience. Scientific management experience essential. Pennsylvania. V–355.

**Chemist** who has actual practical knowledge of manufacture of aluminum sulfate. Man who has experience and can go right ahead with commercial process. Apply by letter. New Jersey. V–622.

**Mine Superintendent.**—Thorough practical working knowledge of Spanish language and experience in handling Mexican workman. Graduate mining engineer. Personality and executive ability sufficient to organize, direct, and efficiently operate group of mines producing approximately 600 tons of ore per day. Must have had experience in handling heavy ground. Must be diligent and enthusiastic worker. Send full record of past experience, education, and qualifications. If married, state whether applicant would wish to take family to Mexico. Attach photograph if possible. Mexico. V–704.

**Research Chemist and Metallurgist.**—Technical graduate with broad experience in laboratory and research metallurgy and ore dressing. Knowledge of Spanish language desirable, but not essential. Must have knowledge of cyanidation of silver and gold ores; also of concentration and flotation. Send full record of past experience, education, and qualifications, if married, state whether applicant would wish to take family to Mexico. Attach photograph if possible. Mexico. V–705.

**Professor of Chemistry** and assistant professor of metallurgy, to have charge of chemistry department but work in metallurgy under supervision of present professor of mining and metallurgy. Age at least 30 years. Practical experience in chemistry and metallurgy. Electro-metallurgy if possible. Experience in college teaching. Year begins Sept. 1, 1922. Possibly work can be arranged for man to teach chemistry during summer session, outside regular contract. Apply by letter. New Mexico. V–706.

**Solicitor** who understands foundry practice to solicit jobs in non-ferrous castings. Apply in person. Salary and commission. New York City. V–747.

**Practical Builders** for small stone residences. Small investment necessary. No foreign language necessary. Good climate. Apply by letter. Dutch West Indies. V–752.

**Mine Foreman.**—Three years contract. Transportation paid both ways. South America, high altitude. Apply by letter. V–785.

**Mine Shift Boss.**—1920 graduate will be considered. Three men needed. Three years contract. Apply by letter. South America, high altitude. V–786.

**Mining Engineer** with safety and industrial relations experience for copper smelting and refining plant. New Jersey. V–809.

**Mechanical Engineer** or high-class master mechanic to take charge of foundry shops and machinery of large mining company operating in Mexico. Must speak Spanish and furnish good references. Prefer one who has held responsible position in mechanical department of large mine in Southwest or Mexico. Salary commensurate with position and experience. Apply by letter. V–818.

**Sales Manager.**—Desires to enter partnership with manufacturer to build up business. Willing to invest capital and take entire charge of marketing product. Age 37. V–762.

**Metallurgist** familiar with iron and steel research work. Age 35. New York City. V–906.

**Chief Mine Engineer,** Maryland Bureau of Mines. Salary five thousand. Apply to State Employment Commission, 22 Light St., Baltimore, Md. V–1080.

---

**Specifications** for the various refined petroleum products purchased by the Federal Government are given in Technical Paper 305, just issued by the U. S. Bureau of Mines. The specifications cover motor gasoline, aviation gasoline, naphtha, kerosene, signal oil, fuel oils, lubricants, etc. These specifications have been officially adopted by the Federal Specifications Board. They supersede the specifications published in Bulletins 1 to 5, inclusive, of the Committee on Standardization of Petroleum Specifications.

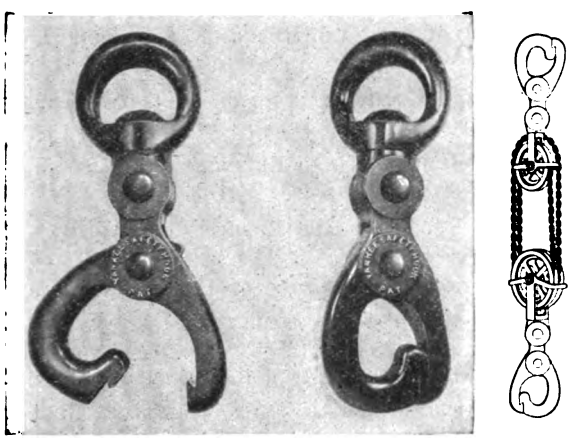
# Industrial News and Developments

Devoted to manufacturing and trade news of interest and value to the mining and metallurgical industry and invited from manufacturers and dealers. Scrutinized but not vouched for by the Institute.

## Safety Hoist Hook

AN INTERESTING form of hoist hook is made by the Frank W. Trabold Co., 30 Church St., New York. It is called the Yankee safety hook and is made in five sizes, from 1 to 25 tons capacity.



YANKEE SAFETY HOOK, OPEN, CLOSED AND ATTACHED TO A CHAIN HOIST.

This hook cannot straighten out nor unlock while under tension. It cannot be attached to a load unless it is locked into position, and cannot be unlocked until the load is safely landed.

The body parts are drop forged from high-grade steel, and Monel metal rivets insure high resistance to shearing strain.

## Caterpillars for Railroad-type Shovels

THE Bucyrus Co. of South Milwaukee, Wis., announces that it is prepared to equip all sizes of railroad-type shovels with caterpillar traction.

This mounting consists of two forward caterpillars, replacing the jack arm, and two rear caterpillars mounted under the rear of the shovel.

The front caterpillars are designed to swivel and adjust themselves to unevenness of the ground. Both front caterpillars are drivers.

The rear caterpillars consist of two units mounted on the same frame. They are strong enough to cross holes and ditches without the delay incidental to filling in.

Steering is done through the rear caterpillars. The massive steering arm is integral with the pintle of the rear caterpillar trucks. It carries a heavy gear segment which engages a pinion on a vertical shaft. It is driven by an independent center valve, reverse type engine, suspended underneath the car frame. This engine may be operated either from the operator's stand or from ground alongside the rear caterpillars.

Propelling is done by the front caterpillars. These may be driven together or each one independently, forward or backward. The propelling speed is about ½ mi. per hr. The tractive power is sufficient to enable the shovel to climb with ease 15 to 20 per cent. grades.

Over one hundred caterpillar-mounted Bucyrus machines weighing from 65 to 220 tons have been sold within the past eight years and are operating with unqualified success.

## Industrial Notes

**Combustion Engineering Corpn.,** New York, announces the opening of a branch office at 1137 Guardian Bldg., Cleveland, Ohio. This office will be in charge of Frank Henderson, who has been with stoker companies in that territory for many years.

**Minerals Separation North American Corporation.**—John Ballot, president of the Corporation, died on April 1.

**Uehling Instrument Co.,** manufacturers of $CO_2$ recorders and other fuel economy equipment, may now be reached at 473 Getty Ave., Paterson, N. J., instead of at 71 Broadway, New York.

**Dayton-Dowd Company, Quincy, Ill.,** manufacturers of centrifugal pumps, announce that A. P. Blackstead, formerly chief engineer of the Camden Iron Works, Camden, N. J., and prior to that hydraulic engineer with the Henry R. Worthington Co., New York, has joined the engineering staff of the Dayton-Dowd Company. Mr. Blackstead has had broad experience on centrifugal pumps for over 20 years, in this country and abroad. He recently returned from Europe, where he spent six months studying conditions and investigating recent developments in hydraulic engineering.

**Vanadium Corporation of America,** 120 Broadway, New York, about two years ago began an extensive series of tests and research to produce better drill steel, and has recently issued a condensed report of comparative tests on vanadium drill steel and FJAB Swedish steel. The report shows superiority of vanadium steel over the Swedish steel in resistance to failure from shock and fatigue.

## Trade Catalogs

**Deppé Motors Corpn.,** 151 Church St., New York.—Folder on Deppé Superheat System for operating Midwest Internal Combustion Engines.

**Aldrich Pump Co.,** Allentown, Pa.—Data No. 27 on Selective Fittings. Described uses and applications of articles that may be used to advantage in connection with the Aldrich pumps.

**Templeton, Kenly & Co, Ltd.,** 1020 South Central Ave., Chicago, Ill.—Bulletin 122, illustrating and describing Simplex Jacks. This bulletin gives information of interest to all users of jacks.

**Uehling Instrument Co., Paterson, N. J.**—Bulletin 112, covering Uehling $CO_2$ Recording Equipment, for guiding the engineer and fireman in reducing the waste of fuel up the chimney. Particular attention is called to the recently developed "Pyroporus" filter, which keeps the gas-sampling lines clean. Other noteworthy features are the separate recorder for the engineer's office and indicator for the boiler-front continuous (not intermittent) chart record and dry method of absorption.

# AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS

Organized 1871. Incorporated 1905

The aims and purposes of the Institute are to promote the arts and sciences connected with the economic production of the useful minerals and metals and the welfare of those employed in these industries.

## OFFICERS AND DIRECTORS

For the year ending February, 1923.

PRESIDENT

ARTHUR S. DWIGHT . . . District 0 . . . . . NEW YORK, N. Y.

PAST PRESIDENTS

HERBERT HOOVER . . . District 4 . . . . . WASHINGTON, D. C.
EDWIN LUDLOW . . . . . District 0 . . . . . NEW YORK, N. Y.

FIRST VICE-PRESIDENT

J. V. W. REYNDERS[3] . . . . . NEW YORK, N. Y.

TREASURER

CHARLES F. RAND . . . . . NEW YORK, N. Y.

SECRETARY

FREDERICK F. SHARPLESS. . . . . NEW YORK, N. Y.

ASSISTANT SECRETARY

PERCY E. BARBOUR . . . . . NEW YORK, N. Y.

VICE-PRESIDENTS

FREDERICK LAIST[1] . . . District 7 . . . . . ANACONDA, MONT.
SEELEY W. MUDD[1] . . . District 10 . . . . . LOS ANGELES, CAL.
E. L. DEGOLYER[2] . . . . District 0 . . . . . NEW YORK, N. Y.
ALBERT BURCH[2] . . . . District 10 . . . . . SAN FRANCISCO, CAL.
J. V. W. REYNDERS[3] . . . District 0 . . . . . NEW YORK, N. Y.

## EXECUTIVE COMMITTEES OF LOCAL SECTIONS

*New York*—ROBERT LINTON, chairman; E. L. GRUVER, sec.-treas., 25 Broad St., New York.

*Boston*—W. SPENCER HUTCHINSON, chairman; R. B. EARLING, sec.-treas., 55 Congress St., Boston, Mass.

*Columbia*—RUSH J. WHITE, chairman; LYNDON K. ARMSTRONG, sec.-treas., 720 Peyton Bldg., Spokane, Wash.

*Puget Sound*—AMOS SLATER, chairman; J. G. MURPHY, sec.-treas., 203 Maynard Bldg., Seattle, Wash.

*Southern California*—HARVEY S. MUDD, chairman; DESAIX B. MYERS, sec.-treas., 433 Merchants National Bank Bldg., Los Angeles, Calif.

*Colorado*—ROBERT HURSH, chairman; HORACE F. LUNT, sec.-treas., 220 State Museum Bldg., Denver, Colo.

*Montana*—WILLIAM B. DALY, chairman; E. B. YOUNG, sec.-treas., 526 Hennessy Building, Butte, Mont.

*San Francisco*—ALBERT BURCH, chairman; C. H. FRY, sec.-treas., 625 Market St., San Francisco, Cal.

*Pennsylvania Anthracite*—R. V. NORRIS, chairman; PAUL STERLING, sec.-treas., Lehigh Valley Coal Co., Wilkes-Barre, Pa.

*St. Louis*—F. W. DE WOLF, chairman; WALTER E. MCCOURT, sec.-treas., Washington University, St. Louis, Mo.

*Chicago*—L. V. RICE, chairman; F. G. FABIAN, sec.-treas., 1025 Peoples Gas Bldg., Chicago, Ill.

*Utah*—HENRY M. ADKINSON, chairman; E. R. PEMBROKE, sec.-treas., Kearns Bldg., Salt Lake City, Utah.

*Arizona*—CHAS. A. MITKE, chairman; I. H. BARKDOLL, sec.-treas., Box 1414, Globe, Ariz.

*Nevada*—JOHN G. KIRCHEN, chairman; HENRY M. RIVES, sec.-treas., 210 Reno National Bank Bldg., Reno, Nev.

*Mid-Continent*—H. B. GOODRICH, chairman; R. S. MCFARLAND, sec.-treas., Tulsa, Okla.

*Washington, D. C.*—SIDNEY PAIGE, chairman; JOHN ALDEN DRIMES, sec.-treas., 3800 14th St., N. W.

*Pittsburgh, Pa.*—FREDERICK CRABTREE, chairman; S. L. GOODALE, sec.-treas., Univ. of Pittsburgh, Pittsburgh, Pa.

*Mexico*—(Institute Mexicano de Minas y Metalurgia.)—VICTOR M. BRASCHI, chairman, Committee on Organization.

*Wisconsin*—R. S. MCCAFFERY, chairman; A. E. DRUCKER, sec.-treas., University of Illinois, Urbana, Ill.

*Ohio*—ZAY. JEFFRIES, chairman; C. B. MURRAY, sec.-treas., Perry Payne Bldg., Cleveland, Ohio.

*Minneapolis-St. Paul*—W. R. APPLEBY, chairman; LLOYD D. COOPER, sec.-treas., 110 Security Bldg., Minneapolis, Minn.

*Northern Minnesota*—W. G. SWART, chairman;,B. A. CONCKLIN, sec.-treas., Hibbing, Minn.

*Upper Peninsula*—WILLIAM KELLY, chairman.

*Oregon*—HENRY M. PARKS, chairman; P. R. HINES, sec.-treas., 903 Lewis Bldg., Portland, Ore.

*Philadelphia*—HENRY S. DRINKER, chairman; F. LYNWOOD GARRISON, sec.-treas., 982 Drexel Bldg., Philadelphia, Pa.

*Northern Arizona*—ROY MOORE, chairman; R. S. BILLINGS, vice-chairman and sec.-treas., Kingman, Ariz.

*Northern West Virginia and East Kentucky*—J. K. ANDERSON, chairman; C. E. KREBS, sec.-treas., Union Bldg., Charleston, W. Va.

## EDITORIAL

### How do Things Stand in Europe?

IN THIS magazine for April, I reviewed the economic position in the United States, as it then looked to me. Nothing has happened since then to induce any modification of my views. Now, as the Genoa conference draws to a close, it is important to examine the situation in Europe, for regardless of the contempt for foreign trade that some thoughtless persons profess, and the *insouciance* with which many seem to think that the United States can "go it alone," leaving Europe to muddle in its own mess, the sober fact is that our fortunes are intertwined with those of Europe irrespective of whether we like it or not.

It is now three and one-half years since the Armistice. Hypothetically, a good deal of readjustment should have been accomplished in that time; practically, this could not begin immediately. In our own country the immediate aftermath of the war did not come to an end until the middle of 1920, and we did not begin to appreciate the stern realities until about the following November. We are not three and one-half years along with our readjustment, but only about one and one-half years. Something like this, also, is the case with Europe. Many of its countries did not appreciate what was confronting them until their American credits were exhausted (about the middle of 1920), which precipitated our own debacle.

It is commonly agreed that the prosperity of a country, like that of an individual business, is a function of its productivity. Unfortunately, the latter can not be easily measured for a country. If it could be done at frequent intervals we should have means for determining the state of general business. It is attempted, in default of any better method, to do this indirectly, by examining such data as bank clearings, car loadings, the production of some basic commodities, etc., and perhaps by making composites of such data. Reflection will lead to the conclusion, however, that none of those factors has an inherent coincidence, or true correlation,

Digitized by Google

with general productivity. But there is one which does possess such a correlation and that is the employment of labor. Production is indeed a direct effect of the exercise of labor. Not only is this theoretically true but also have statistical comparisons between physical production and labor employment proved it to be true.

In considering mere statistics of numbers employed, however, it is necessary to introduce modifying factors, which may be characterized as factors of efficiency and which may be plus or minus. We may not be able to determine those factors numerically, but we can generally form ideas of their nature. This is prefatory to reporting the observation that in most of the industrial countries of Europe the percentage of employment is still very low, that in none of them has there been exhibited any strong tendency toward increase, and that in some of them things have manifestly been going from bad to worse. Let us now examine the positions with some detail, for in them we shall find much of what disturbed the Genoa conference and also much that has a direct bearing on our own affairs.

In Great Britain the rate of employment was high during 1919 and 1920, but in the latter part of 1920 it dropped precipitously to about the middle of 1921, when a minimum of about 80 per cent. was reported. Following this there was a slight increase during several months and then another decline to about 81 per cent. Since the beginning of 1922, there has been a slow increase. Along with this there has been an increasing volume of physical production, an improvement in sentiment, a rise in the stock market, and, in short, an exhibition similar to what we have concurrently experienced in the United States. The percentage of employment and the volume of business in Great Britain are still very subnormal, however.

In Belgium, the line followed a similar course during 1921, but from the depth of depression in that year there has been a pretty steady upward movement.

In Sweden, on the other hand, things started sharply down hill in the latter part of 1920 and have continued to go down ever since.

Germany showed a fairly high rate of employment throughout 1919 and 1920 and during the second half of 1921 attained a very high figure indeed, but there has been some recession from the peak attained in October, 1921.

Definite data are available only from the foregoing countries, but general information from other countries is of similar character. The situation in Spain has been becoming increasingly bad. In Italy and Switzerland, also, it has been bad. In Austria, it has been, and still is, chaotic. In France, there appears to have been a high rate of employment. The countries of southeastern Europe seem to have been getting on pretty well. Russia, of course, is in a desperate way.

It is now necessary to modify the data of numerical employment by the factors of efficiency. In a general way it may be declared with certainty that the efficiency in every country of Europe is subnormal, *i.e.*, if the production of 3000 work-hours per man under pre-war conditions were 100, the present rate of production is a percentage thereof, varying in the several countries. This is a consequence of malnutrition and impairments resulting from the war, of unsound economic spirit and of unwise legislation.

In Germany, although the rate of employment is high, the efficiency of work is low. This is brought about by the several evil factors that have been mentioned, among which, under the head of unwise legislation, is to be included the 8-hour day. One of the first edicts of the revolutionary government in 1918 was to fix a daily working time of 8 hours and a weekly time of 48 hours. By arrangements between employers and trade unions, the latter representing more than six million workers, a working time of less than 48 hours per week has been established in a large part of the mines and factories. The German Government is now considering replacing the decree by a law, but the employers are protesting, representing that in most industries the expected increase in productivity has not been realized, but that on the contrary there has been a falling off, and they attribute this materially to the 8-hour day.

In France, also, with a high rate of employment, there has been a similar deterioration in work done, and this too is ascribed largely to the 8-hour day, which on Apr. 23, 1919, was made mandatory in all branches of industry. The hypothesis that the worker would be so invigorated by rest and relaxation that he would do in 8 hours more than formerly in 10 or 12 has not proved to be true, if we may rely on the conclusions of a distinguished French economist. On the contrary, the reverse has been the fact, the output having become smaller in quantity and poorer in quality. Data recently presented in the Chamber of Deputies showed reduced production in various industries ranging from 20 to 40 per cent., all ascribed to the 8-hour legislation.

In Great Britain, too, there has been reduced efficiency, but there seem to be signs of a "come-back," by dint of necessity, the British worker apparently becoming appreciative at last of the principle of nature that is expressed in the old homely phrase, "Root, hog, or die." Even is there evinced a willingness on the part of the men to go back to zinc smelting, which had become a dead industry, and not only to accept such work but also to try to be efficient and happy in doing it.

It is only in the small countries of southeastern Europe that there has been any fair degree of recovery from the effects of the war. Their resuscitation is ascribable to their being essentially agricultural countries, rather than industrial, wherefore their scars have been capable of relatively quick healing. Russia, although mainly agricultural, is nearly dead by virtue of its communistic experiment. So long as this prevails, with its stand against private ownership of property,

Digitized by Google

Russia is doomed to eternal poverty. Among the other major countries of Europe, France and Italy do not figure so greatly in the world's economic complex, for the reason that their peoples lead lives that are more or less self-contained. It is upon Germany and Great Britain that attention must focus. Their foreign trades are necessarily large, for their very lives depend on their people working for those in other parts of the world. They must take in great quantities of food and raw materials and send out manufactured products. In other words, the main basis for their livelihood is the sale of their work, and conditions preventing that may not only prevent prosperity but also may curtail the ability to live.

Herein we find the explanation of the political maneuvers that exhibited themselves at Genoa. Great Britain is constrained to do everything possible to get the wheels of industry in motion without much attention to any likes or dislikes. Germany, with some of its most important industrial regions trimmed off and with a congested population, must also seize upon any available expedients. An arrangement between Germany and Russia in itself is not to be deprecated, for Russia is a natural outlet for German activities and the development of such will be beneficial to the whole world. The objectionable thing about the Rapallo treaty was its consummation without the supervision of the other powers. France is not under the same pressure as Great Britain, but it is semi-bankrupt and hopes only to survive by obtaining the maximum of reparations from Germany. France, moreover, is determined to preclude the possibility of any further military aggression. Thus the interests of Great Britain and France are quite different and so far no formula for reconciliation has been found.

The Soviet Government of Russia, seeking to preserve itself, is in desperate need of a large loan of funds and its delegates went to Genoa to get it. They were permitted so to play their hand as to make Russia the main issue and incidentally produce splits among the other powers. This was unfortunate, for the immediate importance of Russia to the rest of the world is greatly overestimated. At the moment, it is Russia which needs the assistance.

Our Government in Washington had a keen discernment of these conditions and wisely refrained from going to Genoa. America holds the key to the whole position in so far as Russia is concerned, for no other nation is capable of extending the credits that Russia needs. The American position is clear cut against extending any credit to the present government of Russia. Popular opinion in this country would not sanction any governmental loan and any attempt to finance private loans with a government that does not recognize private rights in property would be preposterous. The American investor would view loans to such a government as equivalent to giving away his money.

It is an illusion that the redevelopment of Russia will contribute immediately in an effective way to improving the welfare of the world. For the moment, it is Germany that has the most economic concern with Russia, next Great Britain, and America least of all. The essential conditions for restoring commerce and industry in Europe and upholding a decent scale of living for the several peoples are an assurance of peace, a fixing of German reparation payments so that they can be met in a reasonable way, a balancing of budgets by every government, and the inauguration of rigid economy by everybody. But underlying everything else is the need of harder work and more productivity in all quarters. "There is one remedy—an infallible remedy—that will solve all our world problems," said Lord Leverhulme, recently, "and that is work, and then more work, and then to forget that there is such a thing as a problem." During the war there crept into the minds of people, both in Europe and America, the idea that in some way it was possible to get a living without working, or anyhow without working very hard. This was a reflection of the economic fallacy that there is somewhere a great fund of money out of which wages are paid. This fallacy still prevails. It is encouraging, therefore, to read of J. R. Clyne, the distinguished and very intelligent labor leader in Great Britain, talking to his followers like this: "At present workmen assume a sort of monstrous reservoir from which they can draw whatever wages are desired. If the worker has to choose between more output or less pay, he should be content to pick the former and so increase the purchasing power of his earnings. Unfortunately, in the minds of many workmen there is a lack of even the elemental facts of political economy, a state that the future educational systems must remedy."

W. R. Ingalls.

## Exempting Those Who Don't Want to be Licensed

AT THE February meeting of the New York State Board of Licensing for Professional Engineers and Land Surveyors, appeared a delegated committee of the County Highway Superintendents who saw jeopardy to their jobs in the Licensing Law. They are building 69,000 out of the 80,000 miles of improved highways in New York State, but few of them have engineering training, one of the committee, in fact, being a doctor. The committee informed the Board, in so many words, that it would do better to license them "with your eyes shut" than to have them repeal that section of the law providing that state and county, etc., construction work in excess of $2000 must be done by licensed engineers.

They had taken time by the forelock, and their various friends in the State Legislature had introduced, and there were then pending, eight different bills

Digitized by Google

amending or repealing the section offensive to the political office holders, some of whom had successively retained their elective positions for 13 years.

Members of this committee argued that to have held these positions for such long periods they must of necessity have been doing the work satisfactorily, although they estimated variously that 75 to 99½ per cent. of their time was devoted to general business and caring for political friendships and related matters.

One interesting question growing out of this is: Does ½ per cent. of a doctor's time during, say, 10 years devoted to road work make a highway engineer of him and entitle him to a license as a Professional Engineer?

If there is any virtue in licensing engineers "in order to safeguard life, health and property," it seems evident a most fitting field for its application would be in the expenditure of the public's money in public engineering and construction. However, the Legislature kindly passed an amendment to the offensive section, reading in part "this section shall not apply to the construction, improvement or maintenance of county roads or town highways," thus exempting County Highway Superintendents. If you are a trained engineer, you must take out a license before you may with safety to the public "life, health and property" build state highways, bridges, etc., but if you are a country doctor elected to county highway superintendency you may do highway engineering (*sic*) with only a split-log drag and the complacency born of a solid constituency. How much of the public's money might have been saved, might yet be saved, if all county road building, 69,000 miles, were to be done by trained engineers?

There were only 57 of these county highway superintendents for whose benefit this amendment was enacted. What possibilities are opened up for other groups of more numerous engineers, the mining engineers for instance, who are also opposed to licensing based on much firmer arguments than political expediency? PERCY E. BARBOUR.

## Fall Meeting of the Institute

THE Board of Directors, on May 19, voted to accept the invitation of the San Francisco Section to hold the regular fall meeting of the Institute in San Francisco.

The week beginning Sept. 25 has been chosen as the time for this meeting. It is hoped that a program will be sufficiently advanced to enable a more detailed statement to be printed in the July MINING AND METALLURGY.

Members will please bear in mind that all announcements respecting the fall meeting will reach them through the pages of MINING AND METALLURGY, at the regular intervals of its publication.

FREDERICK F. SHARPLESS.

## Our Greatest Investment

AT THE February meeting, the president, under specific authorization of the Board of Directors, appointed a committee of five to coöperate with the War Department in the matter of Industrial Preparedness with particular reference to war minerals, but in the widest significance.

The Institute's activities in the matter of preparedness in time of peace should not be limited to the efforts of five men and a patriotic president, despite the considerable results we may confidently expect them to accomplish. Too many of our members served in the army as engineers in the last war to have the emasculation of the present army and our National Defense Act a matter of no concern to them and the Institute now.

Our members are concerned directly and indirectly, through their patriotism, through their mining interest, through their taxes, through desire for adequate protection of their foreign mines and investments, in the blind wave of pacifism which is urging Congress to wreck our present military system.

Would that further wars were impossible, but with present world conditions more pregnant of war than at any time of peace, within memory it is an engineering and economic crime to scrap the only adequate National Defense Act we ever had. Read Upton's "Military Policy of the United States" if you would learn how near ruin we have come in every war, despite the undisputed and unequalled valor of the American soldier, because we had a weak, vacillating policy or none at all. A moiety of the money we are still spending as the result of mistakes in past wars, if now spent in adequate preparedness, would do more to make future war impossible than any other course the human mind has conceived.

Putting aside, if you will, all thought of humanism, race advancement, and all the altruisms we dream of or aspire to, it means more to your personal comfort, happiness and your own pocketbook to spend a dollar to prevent war by suitable preparedness than to go through what we are going through now in post-war costs, taxes and troubles which take all the dollars the members of the profession can now earn.

This preparedness can be accomplished cheaply if Congress can be made to see that the people of this country want it. And to whom is Congress most responsive? To the communications from constituents.

President Dwight's committee of five will spend many hours working on questions vital to you and your hopes and projects and prosperity. You can help them vastly by spending a few minutes dictating a few letters to your Congressmen and Senators, telling them you and your community want proper preparedness. Legislators never were as heedful of the mandate of popular opinion as now.

PERCY E. BARBOUR.

# Review of the Month

MAY began with a general strike of the bituminous and anthracite coal miners in the United States in progress, while in Great Britain about three quarters of a million workers became idle by a lockout, caused by a dispute respecting the question of the rights of management in their shops. The employers opened their shops on May 3 to men wishing to resume work, but few availed themselves of the opportunity. Up to this time the statistics had been showing a little increase in the rate of employment in Great Britain and business conditions were considered to be improving.

From Russia came reports that the results of the famine had not been so bad as had been prophesied, which is not to say that they were not grievous. In prognostications such things are habitually overestimated. Seeding for the new crop has now begun in Russia, with hopes for better results than last year. However, the general economic situation in Russia steadily becomes worse. We had advices during May to the effect that the Soviet Government had decided to abolish the gold ruble even as a theoretical calculating unit and substitute a "goods index." This idea would be somewhat on the lines of Professor Fisher for stablizing the dollar, and there may be a chance to see how it will work in practice. There was a contradictory report from Russia, however, that it had been decided to revert to the gold basis. This is the more plausible report, for if there be anything to be deduced from economic theory and history the present paper rubles will completely collapse and return to gold basis will ensue simply because the people will refuse to sell their goods on anything else.

The civil war in China came to a head during the first week in May when General Wu-Pei-fu crushed the forces of General Chang Tso-lin around Pekin. The victor declared his intention to be to reunite the North and the South and in course of time to arrange for a constitutional convention. We probably do not understand the conditions in China, but recent events do not appear to have solved the grave difficulties there, though they may be a step toward it. However, the immediate outlook does not appear good, General Chang having retired to the north and declared the secession of Manchuria and Mongolia.

In the south of China there have been troubles, financial and otherwise. We do not reconcile all of this, however, with the better buying of silver from the Orient, which put up the price to 72¾ cents. Of course, this has been due largely to India, which is now able to draw gold from either England or America, evincing thus an increased purchasing power.

The Germans replied to the Reparation Commission's note of last March, saying that the commission's demand for sixty billion paper marks of new taxation cannot be complied with "before May 31," but that Germany is prepared to submit before that date "a complete scheme to cover expenditure without further monetary inflation." The reparation payment of 15,000,000 gold marks, due May 15, was made on that date.

The great event of May was, of course, the Genoa conference. Right from the beginning this resolved itself into an attempt to arrange some understanding with Russia, rather than a consideration of general economic conditions. A state of consternation developed when a separate treaty between Russia and Germany, surreptitiously negotiated, was announced. This was viewed by the great powers as a breach of faith on the part of the Germans and may be annulled by *force majeure*. However, things were smoothed over temporarily and negotiations proceeded, with strong prospects of disruption of the *entente* between Great Britain and France, but finally the Russians made such an impossible reply to the allied overtures that everyone united in the opinion that there was nothing to be done and the conference came practically to an end.

There was a proposal to wind up the Genoa Conference and resume conversations at the Hague in June with the idea of appointing a commission to investigate Russian affairs. The United States was invited to participate in the conference at the Hague, but Washington refused on the same grounds as previously. This met with the hearty approval of France.

An event of much importance to the metal industry was the signing at Geneva, May 15, of a treaty between Germany and Poland arranging the economics of Upper Silesia. The League of Nations award, while providing for the political partition of this great industrial province had recognized nevertheless that its economic unity should be preserved. The new treaty establishes that for the next 15 years the distribution of coal, water power, and electric power, the operation of the railroads, and postal communications are to continue as if Upper Silesia were under a single suzerainty. It is a difficult experiment, but it is necessary for the successful operations of the industries.

In the United States, business has become very good in some branches, fairly good in others, but continues poor in many. There is the greatest activity in building, automobile manufacturing and automobile tire making. The wooden industry is moderately active.

Digitized by Google

Cotton spinning is active in the South, but is slow in New England, even in those places where operations have not been checked by strikes. There is a similar situation with respect to shoe making, which is active in St. Louis and the Middle West, but is very dull in New England.

In agriculture, although there has been an improvement in the position of the farmers this has not been sufficient to overcome their troubles. It is to be borne in mind that the rises in prices for agricultural products came after last year's products had passed largely out of the hands of the farmers and had been largely consumed. Moreover, the recent advances in the prices of cotton, corn and wheat have been more or less in anticipation of poor harvests this year.

Business failures have declined slightly although they are still abnormally high. Retail trade is not active in any part of the country and recently has exhibited declining tendencies. The last mentioned feature is in accordance with another factor which makes a negative instead of a positive sign, *viz.*, the decline in the Federal reserve currency that is in circulation, there having been a reduction of about $286,000,000 from the first of January to the end of April this year. This implies a contraction of cash turn-over, not an expansion. Other data raise the question whether business has really improved so much as in building houses and motor cars.

The increase in the volume of the iron and steel business is of course directly explained by the increased building of houses, manufacture of automobiles and to a less extent the increased construction of locomotives and railway cars.

The behavior of the metal markets is a direct reflection of the events as hereinbefore outlined. Lead has been distinctly the strongest of the principal metals. It is called for extensively in house building, both for painting and plumbing. It is called for, moreover, in automobile construction and operation.

For the same purposes steel is especially in demand. House building does not call for very much copper. Automobile construction requires a good deal, but the increased demand for copper from that quarter has been to a considerable extent offset by the decrease in shipment. The electrical manufacturing industry, which is the great mainstay for copper, has shown a little improvement, but not very much.

Commercial loans by the banks that report weekly to the Federal Reserve Board have shown a reduction from $9,326,000,000 at the beginning of 1921 to $7,271,000,000 at the middle of April, 1922. Since Jan. 1, 1922, the reduction has been relatively slight. This may be interpreted as meaning that compulsory liquidation of stocks of goods has been substantially completed. It does not mean, however, that stocks of goods have been reduced to the point from which a general replenishment will be required, but it may be assumed that of what remains the holding will be more comfortable, without there being banking pressure for further liquidation which would lead to renewed cutting of prices.

The coal strike, that has now been in progress for nearly two months, has caused but little industrial disturbance so far. Accumulated stocks of anthracite have not had to be drawn upon. Bituminous production in the non-union fields has increased to nearly 4,500,000 tons per week and this is estimated to be about 60 per cent. of present consumption. The deficit is supplied out of stocks, estimated at about 66,000,000 tons to begin with.

In many parts of the country there are strikes, which are increasing in number. A matter of concern to the metallurgical industry was a strike in the Perth Amboy district, which shut up two of the large copper refineries for a week. The progress of events is steadily confirming the forecast that 1922 would be a year of extensive and widespread labor troubles.

The U. S. Railroad Labor Board on May 11 delivered a decision that the contract, or "farming out" system of railway work, thus removing workmen from the board's jurisdiction, is illegal. This means that the railway companies must pay to unionized labor more than do other employers of the same kind of work if the Labor Board says so.

Just before the middle of May a surprise was sprung by the acquisition of Lackawanna by Bethlehem Steel company. This was followed June 1 by the announcement of a plan whereby the properties of the Midvale Steel and Ordnance Co., Republic Iron and Steel Co., and Inland Steel Co., will be unified under ownership of Midvale. The name of the new corporation probably will be the North American Steel Corporation.

Reports from South Africa indicate a gradual recovery from the recent strike in the Transvaal. Mining operations are restricted by a shortage of native labor. Recruiting is proceeding but it will take some months to restore the full complement of men.

An important event of May was the announcement that Utah, Ray, Chino, Nevada and Butte & Superior have compromised out of court the froth flotation patent litigation with Minerals Separation, and have become licensees. Settlement was based upon the principle of a reasonable license fee for use of Minerals Separation process without any penalties of any kind for past use and is retroactive, *i.e.*, these companies have agreed to pay the royalties that would have been due from them if they had taken out licenses in the first place, just as was done by Anaconda and many other companies. Thus ends the most spectacular, and perhaps the most costly, patent litigation in the annals of metallurgy.

The 10% freight rate reduction ordered by The Interstate Commerse Commission was accepted by the thirty-seven railroads of the Eastern Division. The new rate becomes effective July 1.

The United States Railroad Labor Board announced a reduction in railroad wages of about 13% effecting about 400,000 maintenance of way men also effective July 1.

# The Teapot Oil Affair

By CHESTER W. WASHBURNE
Consulting Geologist, New York City

LEASING the Teapot dome to the Mammoth Oil Co. is the culminating anticlimax of the "conservation movement." It is just the touch required to make a full fiasco of the whole affair. If the revered wielder of the "Big Stick" were still with us, we could hear it fall harder than it did on Ballinger.

Of all the oil reserves set aside by presidential decree, there was only one which certainly could conserve much oil for the future. This was Naval Reserve No. 3, on the Teapot dome, Wyoming. After secret negotiations, carefully guarded from the press and from the knowledge of other oil men, we are suddenly informed that this last and only known chance to save much oil for future naval needs has been given away for early development.

### Drainage of Teapot Dome Limited

It is said that the Naval Reserve would be drained by wells drilled in the Salt Creek field, which occupies a larger neighboring dome immediatly north of Teapot. Such drainage may be admitted for only a very small percentage of the oil in the Second Wall Creek sand. In the First Wall Creek sand the two domes are separated completely by water. The Second Wall Creek sand, on the other hand, appears to carry oil down to or a little below the level of the sag separating the two domes. It is apparent, therefore, that complete drilling of the south end of the Salt Creek dome in the sag would in time drain some oil from the Second Wall Creek sand of the Teapot dome, unless, as Wegemann suspected, there may be faults across the sag which seal the Teapot dome.

The wells especially important in this connection are the wells of the Glenrock Oil Co. along the west line of Sec. 16, T. 39 N. R. 78 W. These are the lowest Second sand wells on the structure, except the Cosden well farther north. They all lie slightly below the level of the saddle or sag that separates Teapot. They all had water in the First Wall Creek sand and oil in the Second, but are only small wells, due to the eastward thinning of the sand. A recent completion by the Fensland Oil Co. in Section 20-39-78, only one-half mile southwest of the Glenrock wells, had 30 ft. of Second Wall Creek sand and is flowing between 500 and 1000 bbl. per day. This well lies about three-fourths of a mile northwest of the sag, and is not much higher structurally. It leads one to infer bigger wells than have been predicted in the Second sand of the Teapot dome.

From the elevation of the sand in these wells, it seems probable that the Second Wall Creek sand carries oil all the way across the saddle separating the Salt Creek dome from the Teapot dome. In that sand the two fields will have a narrow connection. The connection will be shallow, extending only slightly below the elevation of the saddle. The amount of oil that Salt Creek wells possibly could drain from the Teapot dome would be limited to a part of that lying below the lowest closing contour of the Teapot dome. It might possibly be as much as 10 per cent. of the total Teapot oil. When approximately this amount has been drained, the salt water in the Second sand will have risen to the level of the saddle, completely shutting Teapot from further drainage toward the north.

The thinning of the Second sand toward the east indicates that it is not likely to hold much oil on the lower east side of the Teapot dome. Only a little oil from the north end of the west flank is likely to be drained by Salt Creek wells. To save this drainage, roughly estimated at 10 per cent. of the total, the Secretary of the Interior has leased Teapot for immediate development. If the Teapot dome contains reserves of 30,000,000 bbl., as conservatively estimated by Wegemann, the Government is now to surrender this whole reserve for the avowed purpose of saving only the royalty on a possible 3,000,000 bbl., or say about 400,000 bbl., from going into private hands. Actually they are giving many millions of barrels to "private" hands, if that adjective can now be applied properly to the Standard Oil crowd.

### Teapot Only Real Reserve

One cannot blame Secretary Fall for lacking sympathy with the conservation movement. Every practical Westerner and Alaskan knows that the movement has cost his region in compound interest alone many times more than any possible benefit to the rest of the country. Protection from forest fires could have been secured by less stagnating methods. In the case of oil lands, the whole administration of the withdrawals has been a failure. It has conserved practically no oil for the future except in this Naval Reserve at Teapot; it has been merely a nuisance to the operators; it has been grossly unjust to locators of oil "placer claims" when they finally discovered oil on one claim only to have the Government slap a withdrawal order on all other claims. The operators circumvented the unfair withdrawals by costly litigation. The administration of the whole

Digitized by Google

affair has been a practical failure, doing harm rather than good.

There was much greater justification for the Teapot oil reserve, which is one of the three parcels of probable oil land set aside to safeguard the future of the Navy against the time when oil supplies will become inadequate. That time remains far removed from the present, which is one of overproduction. In fact, I believe that for at least another generation the oil industry can supply the Navy with all the oil it needs in war or peace. After that the time is expected when the shortage of oil will be exceedingly serious. It may come sooner, but it will come long after the Mammoth Oil Co. has drained most of the oil from Teapot dome, if the present contract is allowed to stand. One may predict that with the increasing demand for crude oil, at least three-fourths of the total reserves of the Teapot dome will be exhausted in the next 10 years.

### Safety of Nation Threatened

If the lack of oil should contribute to our losing a war 20 or 50 years from now, with all the terrible consequences that would result, those responsible for giving away now our one last undrainable reserve will be linked in history with Aaron Burr.

Those who retarded the free natural development of the West with their ill-founded theory of conservation cared nothing for that important element of national wealth that arises from early industrial development. They never stopped to consider that the rings on a tree grow more slowly year by year while compound interest grows ever faster. Nor did they observe the rate of natural reforestation in western Oregon and Washington, where fire protection was the only thing needed. Nor did they stop to think that in tying up the great Western forests they were adding immensely to the value of private timber holdings and to the cost of lumber for home building throughout the country. Nor did they pause to observe that they were withdrawing enough coal land in the West to last the nation for centuries, and thereby merely adding to the value of private holdings and to the cost of coal. It never occurred to them that future generations might benefit more from a great early development of the West than it could from an idle hoarding of enormous areas, on the theory that the future might suffer from the lack of some commodity. Yet we must admit that the theorists who inflicted "conservation" on the country caused serious injury only to the Western states without greatly affecting the Eastern states, while the extremists of the other side now in office, who propose to drain the Navy's best safeguard long before the time of real need, are threatening the future safety of the whole nation.

The terms of the deal are fair and favorable to the Navy as a business proposition. It is not likely that any oil company could do more. The sliding-scale royalties are generous to the Navy. The Navy can accept either cash or an amount of refined products to be stored at convenient seaports which it selects. There seems to be a flaw in the rate of exchange of royalty crude for fuel oil which does not allow the Navy the full value of the royalties to be paid in fuel oil. The Navy, doubtless, will obviate this by accepting part cash and purchasing fuel oil on the market. Some day a deal of this kind would become desirable, but we trust and believe that black day of oil shortage is for a future generation.

The deal is purely a Standard Oil piece of business. If the Standard were not involved, the Midwest Refining Co., a subsidiary of the Standard of Indiana, would not have transferred to the Mammoth Oil Co. its "rights" acquired largely from the Franco-Wyoming Oil Co. to the early "placer" locations on Teapot dome, even though these locations are generally considered invalid. The Mammoth is said to have used these "rights" as giving a sort of priority over other claimants to a lease on Teapot. Of course, if they had been considered valid, the Midwest would have drilled Teapot long ago. Having the dome drilled by a company affiliated with the Standard, such as the Mammoth appears to be, practically assures the construction of the pipe line to connect with the Chicago and sea-board terminals. If the Teapot dome should not produce enough oil, placed in the contract at 20,000 bbl. per day, to justify building the $20,000,000 pipe line, the required oil can be obtained from Standard interests in the Salt Creek field. The latter is capable of doubling its present output of nearly 50,000 bbl. per day, all of which is now refined locally, mostly at Casper and Glenrock. There is an economic loss in the present development of Wyoming refining capacity beyond local needs, which requires expensive rail shipments to distant markets. A large part of the Casper gasoline output is now being shipped in tank cars to Gulf ports for export.

### Independent Operators Fighting Lease

Independent operators, led by the Rocky Mountain Oil and Gas Producers Assn., are fighting the lease. They are ably assisted by Governor Carey of Wyoming and by the Wyoming Senators and Congressmen in Washington. They say that since the present outlet accommodates only 40 per cent. of the potential production of the present wells in Salt Creek, the drilling of Teapot will cause only further local over supply and congestion. Even at the distant time, probably several years ahead, when the proposed Mammoth line is built to the East, there is not likely to be adequate relief for them. The line will transport probably only 15,000 to 20,000 bbl. per day, which is only a small part of the excess of oil now "pinched" at Salt Creek alone. Moreover, drilling is becoming more active in Salt Creek.

They object to this contract, also, because it tightens the stranglehold of the Standard on Wyoming, which

Digitized by Google

it already controls more closely than any other oil region. If the contract had been given to a company that did not fear to reveal its financial composition and relations, which the independents know is only a scheme to hide its Standard affiliations, they would feel more confident that the new pipe line would create actual competition with the Midwest (Standard). The Mammoth, being considered only a Standard-Sinclair affair, is not expected to result in any real competition. The independents would expect better market conditions if the Gulf or Texas companies had been given the contract, though no one knows whether either of the latter would accept it. They say the Government is giving the small Wyoming producer a raw deal in making the contract with a company that will keep him always under the heel of the Standard.

The fair-play spirit of the Westerners is incensed further by the way in which the whole business was conducted behind closed doors as though it had been a naval secret. They would like to know what the Texas Co., the Gulf Oil Corpn., and other strong independents would have done. They could have clubbed together to handle the business themselves. Open discussion and bidding has been the rule heretofore in granting leases on Indian lands, to the great benefit of the Indian. Similar bidding might have been to the advantage of the Navy.

Many doubt the legality of granting a lease on the undrainable part of the Teapot reserve during the present period of overproduction of oil. Since the Naval Reserves were created to conserve oil underground until the time of need, it is contrary to the purpose of the law to release that oil at present, even though the latter law of 1920 placed the matter under the discretion of the President and the Secretary of the Interior. They believe that the President would have been better informed had the matter been discussed freely by the oil fraternity instead of behind closed doors by a chosen few.

### Summary

The essence of the matter is this: Secretary Fall has made a good bargain for the Navy to secure oil reasonably and conveniently for a few years. In doing so, he has deprived the Navy of its only certain oil reserve for the distant future, when it may be much harder to obtain. He has overlooked, therefore, the essential purpose of the Naval Reserves.

The checkerboarded condition of the two Naval Reserves in California makes them useless as reserves, because the owners of alternate deeded sections can drain much oil from the Government land. In those places, efficient reserves could have been created only by commandeering and buying the private holdings. Failure to do this renders the California reserves useless for their intended purpose. There is no apparent reason why they should not be leased now to the highest bidder, as a mere commercial transaction.

Conditions are quite different in Naval Reserve No. 3, or the Teapot dome. There only a negligible percentage of the oil could be drained. The action of the Secretary of the Interior in this case saves the Government its royalty interest, say some 400,000 bbl. worth, say $600,000 in the 10 per cent. of the total oil that might be drained by legitimate private wells. This saving is negligible and even if it were a hundred times that sum, it would be wrong, because it was not the purpose of the Naval Reserves to make oil a little cheaper for the Navy in times of plentiful oil, but to provide against the distant day when the supply of oil will become wholly inadequate.

Secretary Fall has destroyed the only safe future reserve of oil the Navy possesses, in order to save the Government a little royalty on the negligible percentage of the Teapot Reserve that could be drained by private wells. His object is to guard the immediate profits of the Government and ignores the real purpose of the Reserve to hold oil for the distant time of real need. His object might better have been obtained by granting, through competitive bidding, permits to drill offset wells along the short drainable northern boundary of the reserve. This would have safeguarded all of the oil in the Shannon and in the First Wall Creek sands of Teapot and would have drained but little more oil from the Second Wall Creek sand. Instead of this he has given a heritage for a mess of pottage.

---

## Federated Renews Campaign for Department of Public Works

WITH the warning that President Harding is encountering opposition so strong that his efforts at Government reorganization may be defeated "as were the efforts of Roosevelt and Taft," the American Engineering Council of the Federated American Engineering Societies announced that the engineers of the nation would start afresh a nationwide movement for the establishment of a National Department of Public Works.

The statement of the Council is, in part, as follows:

The President of the United States is endeavoring to formulate a program for reorganization of Federal functions according to the precepts that govern the efficient conduct of private business. He is following the principles originally adopted in the movement of the technical men of the country to secure a Federal Department of Public Works.

The President's course was easy until he began to specify the changes that should take place in the Government to conform to these cardinal principles. He is now encountering opposition so strong and well supported that it is feared his efforts may be defeated even as were the efforts of former Presidents Roosevelt and Taft along the same line. The President, therefore, is in need of the friendly assistance of those who have no prejudices, no self-seeking and no special purposes to serve.

The country needs the voices of those who look and think beyond the outer skin. We always have with us the voice of the crowd, too often impelled by unwise leadership and mob psychology. Every little while it is incumbent upon the thinking portion of our citizenship to render public service.

Engineers started many years ago to urge the creation of a National Department of Public Works. Their sole reason was that the country needed, and still needs, the orderly functioning of its public works activities—needs it because our present system

Digitized by Google

involves a huge waste of public funds, high taxes, and retarded public improvements. The principle is self-evident and if the proposed reform were merely an abstract principle there would be no one to dispute its merit. It would have succeeded long ago if it did not interfere with certain official, political and personal interests.

The President himself has set up the slogan, 'more business in government, less government in business,' and there is no reason why the public business should not be conducted with the same efficiency as a modern private business is. The reason why it is not so conducted is that the millions who understand the underlying principles and who recognize the merits have not insisted that it should be done.

As a result of the public works department movement the Government reorganization idea became a plank in the platform of the political party at present in power. Congress created a committee to reorganize Government business. The Federated American Engineering Societies has become officially concerned with the creation of a Department of Public Works. It is apparent that the object can never be achieved unless the broader object is carried through successfully; therefore this organization, as well as all others that believe in efficient procedure and that know and understand the underlying principles, must participate in the entire program of Government reorganization.

Dean Mortimer E. Cooley, of the University of Michigan, president of the Council, recently visited President Harding, to whom he tendered the support of the organized engineers of the nation in matters affecting engineering and allied service.

## Compulsory Working of Patents

AT THE hearing on the Stanley Patents Bill S-3410 on May 1, Emil Gathmann represented the Institute. The Stanley Bill amends the patent law to authorize the granting of compulsory licenses if patents are not worked to an extent and within a time to be determined in each individual case by the Commissioner of Patents.

Edwin J. Prindle, chairman of the Patents Committee of the Federated American Engineering Societies, made a very able presentation of the issues involved, and clearly indicated the danger not only to the inventor, but to industry as a whole, inherent in such revolutionary legislation. Colonel McMullen, of the U. S. Army's patent branch, was heard in favor of the bill, and gave a clear statement of the necessity which he believes exists to compel foreign citizens holding U. S. patents to work, or allow of the working of, said patents.

Undoubtedly, the Senate Committee will not report the Stanley Bill until there has been opportunity for further discussion and consideration by those interested in the measure, but even if this bill is killed, the substitutes that will probably be proposed will also need careful consideration.

## International Mineral and Metal Statistics

THE International Chamber of Commerce, through its committee on statistics, wishes to secure from business men statements of their requirements for statistics of international trade and production. The Bureau of Foreign and Domestic Commerce desires to aid this committee and therefore wishes to enlist the help of the coöperative committees of trade associations and individuals in securing this information for their particular industries. The purpose of this inquiry is to obtain information that will guide in the improvement of present facilities, both as to the kind of statistics needed and the form in which they are published.

The Bureau of Foreign and Domestic Commerce, Fuel Division, Washington, D. C., will be glad to receive from producers and consumers of ores and metals information on the following points:

1. To what extent does your industry find international statistics of trade and production inadequate for present needs?
2. Do you now make use of any of the sources of international trade statistics? If so, in what respect are these insufficient as to content or as to form? What features are of most value to you?
3. Have you any suggestions to make as to the kind of international statistics that are needed for the various mineral and metal industries, and the form in which those should be issued?

## International Engineering Congress

BRAZIL will celebrate the hundredth anniversary of her independence in September, 1922, in an international exposition at Rio de Janeiro. In connection with the exposition, an international engineering congress will be held, to which the engineers of the United States are cordially invited.

Word has been received, through the Brazilian Commercial Attaché at Washington, that the Brazilian Government approves the International Congress of Engineering at Rio de Janeiro for next September, and that steps have been taken towards all necessary preparations.

The program of the Congress will include discussions on: The utilization of fuel resources; the best utilization of water power; recent advances in irrigation methods; the elimination of waste through the standardization of supplies for agricultural and industrial purposes; coal as a factor in industrial development; essentials of a national railroad policy; intercontinental engineering coöperation; port developments; terminal facilities; the iron and steel industry.

Representatives from American engineering societies will receive credentials from their respective societies.

Mining engineers who expect to be in Brazil during the time of the exposition are urged to notify the secretary of the Institute, so that they may be provided with all necessary credentials and information.

The Secretary of the Interior has designated Thomas T. Read, chief of the Information Service of the Bureau of Mines, as the representative of the Interior Department on the executive committee which is to coöperate with the Commissioner General, Col. D. C. Collier, in making arrangements for a suitable exposition of the activities of the Government of the United States.

# Bituminous Strike Situation

By EDWIN LUDLOW

Consulting Engineer, New York City

ONE of the most unusual features in connection with the strike of the union coal miners in the bituminous fields, now in its sixth week, is that the public interest seems to have completely died out. There is nothing on the front page and very little on any other page of the daily newspapers in connection with the strike. The United Mine Workers' officials must be rather disappointed to find that the only way in which they are being featured in the papers at present is in the reports of the trial for treason that is going on in Charlestown, West Va., against the local leaders of that organization for their responsibility in connection with the attack of the miners' army last summer against the non-union mines of Logan and Mingo Counties.

Recent reports state that there are 13,000 cars of coal standing on the sidings at union mines for which no billing has yet been found. The output of the non-union mines has been gradually increasing but has never reached the maximum that they are capable of producing, owing to their inability to obtain enough orders to make it possible to run full operating time. The present output is estimated at 4,500,000 tons a week. It is possible, with a full car supply and full demand, to bring this output up to approximately 6,000,000 tons per week, and it is very doubtful whether, at this season of the year when probably there is less consumption of coal than at any other season, the requirements of the country are greater than the 6,000,000 tons which the non-union mines are capable of producing. It would appear, therefore, that there is no immediate prospect of any settlement of the bituminous strike, and there is certainly no reason why the operators of the union mines should show any anxiety to begin operations as long as they have unbilled coal standing on their sidings.

## Overdevelopment of Coal Mining

A great deal has been written in the technical and daily press in regard to the overdevelopment of the bituminous coal fields in this country. It seems a little peculiar that the coal industry should be the subject of such sharp criticism in this regard, when conditions in coal mines during the last year have been the same as in other mining industries of the country. Nothing is said about the overproduction of copper, although the large producing copper mines of this country have been absolutely closed down for a year and only now are beginning to resume operations. The same is true to a large extent of the iron region, as the papers are speaking of the opening of iron mines in Michigan at which work has been suspended for over a year. If the large producing coal mines, when the business depression occurred a little more than a year ago, had followed the example of the copper mines, and closed down, there would have been no overproduction of coal.

A great deal has been written also in regard to the seasonal nature of coal mining. This is true, but the work of the farmer is equally seasonal; the glass manufacturers of this country work, on an average, only six months in the year; and yet the coal mine is singled out as functioning so badly because it is not able to sell coal when people do not want to buy that commodity.

## Surplus of Labor and Wagon Mines

With regard to the overmanning of the mines and the possibility of producing the required amount of coal with less labor, and the sufferings of the miners from the three-day week that the mines have been able to average, it must be remembered that the excess of labor is due to the high wages paid the coal miners. Under the union scale, a day laborer receives $7.50 a day; in any other vocation the same unskilled laborer would not be able to earn more than $3. He is better off, therefore, working three days a week at $7.50 than six days a week at $3. As for the contract miner who is able to earn $10 to $20 a day without working even the eight hours, he would certainly have great difficulty in finding any other class of work that would bring him in the same weekly wage, even if he were working full time. The 100,000 men which it is estimated might be taken from the coal industry and put into other lines of employment might possibly be found, if they were able to earn in those other employments as much money as they are now able to obtain even with the short time the mines are in operation.

Another feature in the bituminous industry that has not been taken into account is the "wagon mine." These small operations are usually worked in partnership by miners who are not able to obtain a sufficient output to warrant the building of a tipple and the necessary railroad sidings but who haul the coal in wagons from their drift and slope openings to the nearest railroad station. These mines might be considered "snow birds," coming out in force during times of high prices. The additional expense of the wagon

Digitized by Google

haul makes it necessary for them to obtain about a dollar a ton more than the operator of a large mine is willing to accept. The possible tonnage from these wagon mines, of which there were 7000 at one time at work, would run in the neighborhood of 100,000 tons per day. If the strike continues and the price of coal advances, these wagon mines will undoubtedly spring up in practically all sections of the mining field.

### Ten-year Increases in Bituminous Coal Output

In the year 1880, the output from the United States was 51,200,000 tons; in 1890, it was 120,000,000 tons, an increase of 150 per cent. for the 10-year period. In 1900, the output was 200,000,000, an increase of 66 per cent. for the 10 years. In 1910, the output was 390,000,000, an increase of 95 per cent. and in 1920 the tonnage had reached to 575,000,000 tons, an increase of 48 per cent. The average shows that the output of coal doubles every 10 years. The last 10-year period, however, would indicate a slowing down, due to the greater use of fuel oil and electricity, but, according to the law of averages and the continual growth of this country, we should find that with the revival of industry, our annual output should reach to 750,000,000 tons, and when it does, the output will have caught up with the mine development of the present day.

The present so-called overdevelopment is the greatest protection to the industries of this country in ensuring to them a continual competition in the price of bituminous coal that will always enable them to obtain their fuel at a minimum cost commensurate with the wages that the miners are paid.

As to seasonal fluctuations, a great deal of this could be eliminated if the largest steam users—manufacturers, public utilities and especially the railroads—would make contracts for the fuel based on receiving 50 per cent. of their annual requirements during the four dull months of the year and the other 50 per cent. during the other eight months. The cost of storing the surplus coal received during the four months would be absorbed by the operator in making his price, either by a reduction in the yearly price, or by an allowance on the price for the surplus stocked. The greatest advantage would accrue to the railroads, which would thus increase the available car supply during the winter months, and enable the operator to have a tonnage to meet the seasonal demand of the winter and, at the same time, maintain a continuous output.

### Long-term Contracts Needed

It would be of the greatest possible assistance, also, in the stabilization of the industry if coal contracts could be made for a term of five to ten years. The present short-term contracts reaching from year to year, offer no security for the development of a property. When the contract comes up to be bid upon, it may go to some other mine, which has been able to see its way clear to reduce the price a few cents a ton. A mine that loses a large contract cannot afford to close down and abandon its investment, but will struggle along as best it can hoping that the next year it may secure the contract again. It becomes a continual temptation, in a country that is still so rich in undeveloped resources as this, for operators to open new mines adjoining the old ones, knowing that their costs in the early years will probably be less than those of their neighbors, on account of the greater expense for maintenance of the older and larger workings. This would be eliminated to a great extent if the railroads and larger users would make long-term contracts, as capital would be very slow to invest in a new operation if the tonnage normally mined in that section were contracted for, making an additional market problematical.

### Mr. Hoover's Conference with the Non-union Operators

The commanding feature in the bituminous situation was the meeting in Washington on May 18, called by Mr. Hoover, of the operators of the mines in West Virginia and Pennsylvania which are still producing coal. The decreasing stocks and the increasing demand for coal throughout the country had been reflected in slight increases of the price at the mines and large increases were reported by some consumers who bought their coal through brokers.

Mr. Hoover's plan of bringing together the operators in the open-shop mines is an extremely valuable one, if some legal means can be found by which a combination can be made not only for the protection of the public during times of coal scarcity but for the protection of the mines themselves from unfair competition and the reduction of prices below the cost of production. Unquestionably, there will be a shortage of coal as time goes on, and the great pity is that this could not have been anticipated early in April so as to have allowed the open-shop mines to produce a maximum tonnage.

It would be of advantage to the country if coal could be purchased by the consumer from the producer, instead of passing through three or four hands, each of which takes a heavy toll in additional price, as was the case during the coal shortage of 1920. The price paid should be high enough to stimulate increased operation of some of the high-cost mines in the non-union fields but should not be so high as to warrant any of the union fields in renewing their contracts with the miners on the basis of the exorbitantly high wage which the miners are asking. Every effort should be made by both the Government and the railroads to stimulate the output of the open-shop mines, as upon their ability to prevent a coal famine in this country depends the question as to whether this country can be dominated by union leaders exacting an inordinate wage in their own specialized industry.

# The Anthracite Situation

By R. V. NORRIS

Consulting Engineer, Wilkes-Barre, Pa.

THE wage rates and working conditions in the anthracite region of Pennsylvania have been governed for nearly 20 years by the award of the Anthracite Coal Strike Commission, appointed Oct. 16, 1902, by President Roosevelt. The report of this commission, made in March, 1903, was accepted and, with eight modifications made at various dates, has had almost the force of law, and has kept this great industrial region free from strikes for almost a generation. In 1920, President Wilson appointed an Anthracite Coal Commission, and its report, accepted Aug. 30, 1920, governed wage conditions to April 1, 1922.

Actually, the agreements have been for terms of two to four years, and lately, in 1916 and 1920, the employees have continued at work pending the negotiation of new agreements which were made retroactive, and which have all been modifications of the original 1903 award. With the expiration, April 1, 1922, of the 1920 award approaching, Mr. Lewis, president of the United Mine Workers of America, addressed a letter, on Feb. 20, to the operators, suggesting a meeting on March 15; this date was accepted by the latter, with the notation that the time was short. At the meeting, the Mine Workers presented 19 demands, and advised that if a satisfactory agreement was not reached by April 1 a suspension of mining would occur, contrary to the practice since 1916 of continuing work with a retroactive adjustment.

## Demands of the Mine Workers

The demands were made up of the substance of all those refused by the 1920 commission, coupled with a demand for 20 per cent. increase in contract rates and $1 per day for labor. The granting of all of those, which included many costly jokers, it is estimated by the operators would add $170,000,000 to the annual cost, which, necessarily borne by 53,000,000 tons of domestic sizes, would add about $3 per ton to the cost of coal at the mine.

The demands further include a "standard check-off provision," which has never been included in any anthracite wage agreement, and which was peremptorily refused by both the Roosevelt and Wilson commissions; a demand for a day of eight hours underground, instead of at the working place, really a six-hour day; seniority employment, and lastly "an eight-hour opportunity" to employees or readjustment wages for shorter days—in other words, eight hours pay per day whether worked or not.

These demands have now been discussed for over two months without result, other than to develop a "red herring" in a proposal from the Mine Workers for a commission to investigate conditions, including railroad charges, retail profits, etc., which are not under the control of the operators, coupled with a most unfair preamble practically prejudging the case. The proposal of the operators for a long-term contract, with an arbitration board to adjust wages at intervals, was refused as interfering with collective bargaining.

Finally, the operators have made a counter offer of 18 per cent. reduction in contract rates and $1.20 per day for men and 72 cents for boys on day rates, stated to average 21 per cent. reduction, and to bring the miners' pay down from the 1920 award in proportion to the decrease in cost of living since that time. This it is reported was refused point blank by the miners' vice-president.

## Earnings of Anthracite Workers

The earnings of the anthracite mine workers were exhaustively investigated by the National Industrial Conference Board in a report issued March 20, based on 179 collieries with 91 per cent. of the 1920 anthracite output. The Board finds:

| | Jan., 1914 Cents per Hour | Oct., 1921 Cents per Hour | Increase Per Cent. |
|---|---|---|---|
| All wage earners... | 27.8 | 72.8 | 162 |
| Excluding contract miners..... | 22.5 | 59.9 | 166 |
| | Dollars | Dollars | |
| All wage earners, semi monthly.... | 29.81 | 75.18 | 152 |

The percentage increase for industrial workers, July, 1914, to July, 1921, was 113 per cent.; for railroad workers to October, 1921, 131 per cent., compared with 166 per cent. for anthracite mine workers; the weekly earnings in manufacturing industries, 83 per cent., and for railroads 102 per cent., compared with 152 per cent.

The average hours in the half month were: June, 1914, 107.4; October, 1921, 103.3; with 100 hr. as full eight-hour time, the work has been regular and full as is shown by the great prosperity of the region. The bank deposits in the region have increased from 241 million dollars Jan. 1, 1920, to nearly 322 million, Jan. 1, 1922, an increase of one-third on the total, which does not indicate underpayment.

It is clear that the coal industry could not stand the increased cost that would be involved in even a

Digitized by Google

partial granting of these demands, and the mine workers make no secret of their intention to try and nationalize the industry and then permit the excessive wages to be paid out of the national treasury without increasing the price of coal to the consumer.

The question at issue is: Shall the coal production costs be deflated in line with the business of the country, or shall the price of this necessity be maintained on a pinnacle of cost to permit of the continuance of 17 per cent. more than war wages to one privileged class, the members of the United Mine Workers of America?

## Will the Institute Coöperate with the Department of Commerce?

THE Secretary of Commerce, Herbert Hoover, has addressed a letter to the American Engineering Standards Committee, in which he says:

> There is a steadily increasing interest on the part of leaders of our industries in the great economies that are possible through the simplification of lines of manufactured products. . . . A vast deal of work is going to be required to select and delimit specific problems in form for work. . Will the American Engineering Standards Committee undertake a canvass of the engineering and technical bodies that are coöperating in its work, so as to determine what simplification in manufactured products in their fields is most needed and most desirable?

The Institute's representative on the A. E. S. C., George C. Stone, in transmitting Mr. Hoover's letter to the Board of Directors, asks for the coöperation of Institute members. Please send your suggestions or comments on constructive simplification in your field to the Secretary of the Institute, so that this preliminary survey may be of real assistance to the Department of Commerce in its work.

## Coöperation in Exploration

By F. F. Sharpless

WE ARE publishing herewith a page from a recent work of Dr. C. K. Leith, "Economic Aspects of Geology." We believe that it is of particular significance to the members of the Institute because they possess the opportunity to practice what he preaches. The chief reason for the organization of the Institute was that its members might be "able to exchange technical information." The rapid strides that have been made in this country in mining and metallurgy have been largely due to the fruition of the conception. The members of the Institute have for years exchanged technical information most freely. Doctor Leith says:

> Competition in exploration often develops an atmosphere of suspicion and furtiveness which is highly unfavorable to coöperative efforts. Individuals and companies may handicap themselves greatly by a desire to play a lone hand, and by failure to take advantage of an exchange of information. This action may be based particularly, on the part of strong mining companies, on the assumption that they know all that is necessary about the problem, and that an outsider has nothing to contribute. Financial and other conditions may require this attitude, but in large part it is a result of temperament, as clearly indicated by the difference in methods followed by different groups and in different mining districts. From the scientific point of view this attitude can hardly be justified, in view of the extremely narrow limits of human knowledge as compared with the scientific field to be explored. The sum total of knowledge from all sources is only a small fraction of that necessary for the most effective results. The mutual exchange of information and discussion is usually justified on the basis of self-interest alone, to say nothing of the larger interest to the mineral district, to the country, or to science.
>
> National and state survey organizations exercise considerable effort to secure records of drilling. In some cases they have the legal power to command this information, particularly in relation to appraisals for taxation and "blue sky" laws. In a larger number of cases drill records are secured through voluntary coöperation with explorers. A considerable number of records are nevertheless not filed with public agencies and some of these are permanently lost. Even where the records are turned in to a public organization, they are in most cases not directly available to explorers.
>
> Public registration of all drilling records is a highly desirable procedure in the interests of the development of the mineral industry as a whole. A vast amount of unnecessary duplication can thus be avoided. The record of a drill hole, even though barren, may be of vast significance in the interpretation of future developments and should be recorded as carefully as an abstract of land title. The property right of the explorer in such information can be and usually is protected by withholding the record from public inspection until sufficient time has elapsed to give him full opportunity to use the information to his own best advantage.
>
> The opportunities for coöperation with specialists of public organizations are almost unlimited. These organizations are likely to have an accumulation of data and experience extending through long periods and over large areas, which the private explorer ordinarily cannot hope to duplicate. With proper restrictions, this information may be available for public use. A good illustration of current coöperative effort of this kind is in the deep exploration for oil in the Trenton limestone of Illinois. Outcrops and other specific indications are not sufficient to localize this drilling; but the information along broad geologic and structural lines which has been collected previously by the Illinois Survey is sufficient so that, with a comparatively small amount of shallow drilling, the locus of the more favorable structural conditions may be determined. In this case the Survey is directing the initial exploration, which is financed by private capital.

The oil geologists of Oklahoma are freely exchanging the results of their exploration work. All of the major operating companies in that state possess underground geological maps that are marvels of accuracy, only attainable through the close coöperation of those who have secured the data by drilling.

What the metal miner could and should do is exemplified in what Dr. James Douglas did in respect to his work in the Copper Mine River district in northern Canada.

The writer was once urged to drill a tract of land in the Joplin zinc field. The tract was located on what appeared to be a well defined channel, the ground both to the north and south having been productive. Careful inquiry disclosed the fact that it had already been drilled three times with negative or poor results. Each party had drilled without knowing what the other had found. This was an economic crime. Three times the acreage might have been drilled if the operators had been willing to make their results public, with three times the chance of finding something worth while. We urge upon Institute members the practice of asking freely and of giving freely. It is ethical, and it is profitable.

# Foreign Oil Possibilities and Domestic Price Fixing*

By RALPH ARNOLD

Chairman, A. I. M. E. Petroleum and Gas Committee

IN OPENING the symposium under the auspices of the Petroleum and Gas Committee of the American Institute of Mining and Metallurgical Engineers, I wish to call to your attention the following, among other subjects, which it is hoped may receive proper attention:

1. The recording of as accurate an appraisal of the oil possibilities of the various countries as is possible, with information as to the immediate availability of their supply.

2. The development of further support for the movement to bring about active coöperation among American oil companies in their foreign exploration and development work.

3. The furtherance of the efforts of the industry in securing governmental assistance in foreign oil development: (a) along the lines of a modification of our domestic oil policy, so that we can go to foreign countries and consistently ask fair treatment as to royalties and bonuses; (b) by a closer coöperation between the State and Commerce Departments and the oil industry.

4. The calling of attention to the unjustifiably drastic action of the price-fixing group of the oil industry during the last year or so, with the hope that it will use gentler methods in the future.

None of these subjects are new, and some of them have been discussed before various organizations for years. Our justification for again bringing them forward is the hope that by everlastingly harping on them the industry, the Government, and the people who shape the destinies of this country may some time, some how, realize their importance and take effective constructive action.

It is a source of great satisfaction to many of us that, after a campaign of several years' duration on the part of a group of economic geologists and engineers, the American oil industry has been awakened to a realization that the crude-oil resources of the United States are not inexhaustible; that our crude oil should not be wasted but should be conserved, and used only for those purposes for which it alone is adapted; that every energy should be bent to improve our methods of refining, so that greater and greater percentages of gasoline, lubricants and other more desirable and valuable compounds may be made from the crude oil, rather than dissipated as fuel; and that, as some of the most conservative of the operators have even admitted, there is a possibility in the dim distant future that we may have to resort to our oil shales as a source of supply. No less a person than Thomas O'Donnell said most of these things in public at the recent sessions of the American Petroleum Institute in Chicago, and H. F. Sinclair at the same meeting admitted that we need a foreign supply and just wondered if the industry was willing to pay the price necessary to get it. It is, therefore, no longer *lèse majesté* in oildom to warn of our waning resources and call attention to the need of a foreign supply. Both the scientist and the practical oil man reach exactly the same conclusion and say exactly the same things on the subject—except that the scientist says it about seven years in advance of the operator.

## Coöperation of Government Needed

The second item of discussion, namely, the furtherance of the movement to bring about active coöperation among American companies operating in foreign fields, will probably take the form of suggestions, oft repeated in the past, but brought more forcibly to the companies themselves by the recent débâcle in Mexico, the direct result of cut-throat competition between American companies in that field. Favorable action along these lines of coöperation is now a reality in at least one case.

One of the principal handicaps under which Americans operate in negotiating for oil concessions and leases in foreign countries is the excessive bonuses and royalties exacted by our Government from operators on Government and Indian lands. It is true that in most instances the extremely high bonuses of thousands of dollars per acre, and the excessive royalties amounting to as high as 55 per cent. of the gross production, relate to leases on land proved to be highly productive; but foreigners are not prone to differentiate between proved and prospective land, and hence use these high figures as arguments in favor of impossible terms and conditions in their own cases. I should like to venture the guess that in most instances where these excessive

*Opening address at Symposium on Foreign Oil Possibilities, Feb. 21, 1922.

Digitized by Google

bonuses and royalties are paid, only a trifling profit, if any, is made by the operator. It was my good fortune to help prepare the first draft of the leasing bill, several years before such a bill finally became law, and in these early drafts no effort was made to reserve the lion's share of the profit to the Government, as in the present law. In order to bring this question to a head with Congress, I would suggest a modification of the present law so as to make the maxium royalty 10 per cent., and abolish any but nominal bonuses. The hazards of the oil business are great enough without the Government "taking the last pound of flesh," and the benefit that would accrue to our nationals in foreign fields by reason of reduced royalties and bonuses at home would far outweigh the immediate loss to the Government through the adoption of such a policy.

Coöperation between the State and Commerce Departments is closer than it has been at any time during the past, thanks to the men at the head of these two departments. There is still much to accomplish along the lines of settling matters of contention between domestic companies before they enter the foreign fields, so that whenever American companies go abroad they will do so with a solid front to the men with whom they are to deal. A strengthening of our consular agency and commercial attaché systems would do much to help our foreign oil activities. Information regarding possibilities in new countries or the activities of foreign business rivals in any field is most valuable in advancing our own interests in these countries.

### Power and Responsibility of Price-fixing Group Tremendous

Walter Teagle has endeavored to show by statistics that the foreign imports of oil (meaning Mexican oil) have little effect on the price of our light domestic crude. Mr. Teagle's case is greatly weakened by the fact that the price fixers knocked 70 per cent. from the price of Mid-Continent crude when the great glut of Mexican oil loomed last winter as a menace to our domestic industry but began raising the price again as soon as it dawned on the fixers that most of the proved Mexican fields were doomed to speedy exhaustion. This erratic manipulation of the price caused the ruination of many small operators and independents with a corresponding advantage to the stronger oil companies. In other words, many of our American independent operators and companies were sacrificed on the altar erected by the few producers and importers of Mexican oil. Let us take the most charitable view of the case and assume that the price manipulation was done as a result of panic rather than premeditation.

In order to prevent a repetition of this catastrophe, Congress should bestow upon the President the power to impose a sufficient import duty on oil to protect the domestic industry from disaster when foreign importations appear menacing. By this, I am not suggesting an import duty on oil to harass those companies who are far-seeing and courageous enough to enter the foreign fields, but rather to prevent the dumping which has caused most of our troubles during the last few months. Arguments of the exponents of cheap oil and cheap gasoline may be anticipated by saying that anything, such as these drastic cuts in price, which tends to unstabilize the industry later only assures a higher price to the consumer and a small profit or actual loss to the producer.

The power wielded by the group of men who fix the price of crude oil in this country is tremendous. I think I am disclosing no secrets of the oil fraternity when I say that they sometimes become the "inexorable law of supply and demand" when it suits their purpose. There is also a great responsibility to the rank and file of the producers and consumers and to the general public, if you please, which goes with this power. I, for one, am glad that this power rests in the hands of responsible and tried business men familiar with the vicissitudes as well as with the joys of their industry, rather than in the hands of irresponsible and inexperienced theorists. As long as these business men use this power with justice and discretion nothing should be done to interfere with them, but when they force through as unjustifiably drastic a cut in the price of crude oil as was done last winter steps should be taken to curb their ability to wreak havoc on the industry. I would not place the responsibility for all of our price depressions on this price-fixing group, by any means. Often the producers, large and small, are to blame because of their refusal to adopt programs curbing drilling activities. Furthermore, our present lease system, with its off-set well requirements and compulsory drilling clauses, is a curse to the sane development of many fields. I do want to suggest, however, to the price-fixing group of our industry, in the most friendly way, that they cease using "caveman tactics" and use more discretion, conservatism and magnanimity in regulating the price of crude oil so that they may have the confidence of the industry, the Government and the people. Geologists and engineers through scientific study have become the great factors of conservation in the finding and development of the oil fields; why not apply some of their methods to the price-fixing end of the business?

Again referring to Mexico, may we not say that the oil industry there is "between the devil and the deep blue sea"—meaning, of course, the tax problems on one side and salt water on the other. Only three companies are left in the mad race to empty the last of the important magic pools of the proved light oil field of Mexico. With only 24 wild-cat wells going down outside the proved belt of Mexico in the search for new fields, and none of these at all certain of getting important results, what are we to expect of Mexico in the next few months? When will the crash come and what will be the extent of the damage?

# The Technical Audit

By ALLEN H. ROGERS
Consulting Engineer, New York City

IT IS universal practice for corporations, at the end of the fiscal period, to call in a firm of chartered accountants to audit the books. The effect of this is to put an independent organization's seal of approval on the accounting of the business done by the management. Their report lets the stockholders know that the accounts rendered truly present the results of the year's business. This is as it should be; the average stockholder has no personal contact or even acquaintance with the managers of his enterprise and the approval of their stewardship by an independent agent is very desirable for maintaining confidence in their honesty and ability.

But such an examination deals only with what may be called the arithmetic of the business; even the most elaborate audit, as the practice is at present, goes no further than to verify the items of the inventory. In other words, while checking up the entries showing the transactions of the year and certifying to the correctness of the items of the balance sheet, such a report gives the stockholder no idea of the ability with which his affairs have been managed. If the profit and loss balance is satisfactory, as certified by the public accountants, he assumes that the management has been able; where it is not, he turns to the president's report and usually finds an explanation. Such an explanation never takes the form of admission of mistakes in business judgment or of bad technical management. It could hardly be expected that it would.

The stockholder is generally furnished, therefore, with a certificate of the honesty of his management, but never one of its ability. He does not worry about the latter as long as dividends come in; when they cease, his action generally finds expression in replacing the management. In other words, so long as profits are realized, he assumes the management to be good, even though its success is a matter beyond its control and better management would make larger profits. When there is no profit, the stockholders have no means of knowing whether it is due to conditions beyond the control of the management, as the annual report is sure to allege, or whether, by better management, profit is possible. Here is where the technical audit comes in.

A technical audit is an examination of the operations of the corporation made by an engineer skilled in the particular industry in which the corporation is engaged, with a view to determining the efficiency with which they are being conducted by the management. The report of such an examination furnishes to the stockholders an account of the ability, greater or less, with which the affairs of their corporation are being handled. It furnishes a much more comprehensive view of the results of operations than the financial audit. It shows how the financial results have been attained, how these fall short of possibilities, and in such case how the ultimate possibilities can be attained. Such examinations, made at intervals, do more to keep the management on its toes than anything so far devised. It is what the consulting engineer of a company is supposed to do, and there is no gainsaying the fact that in most cases such an officer aids materially in keeping the local manager keyed up to his best, but the intimacy which sometimes develops between the manager and consulting engineer militates against the best results. As is well known, the management of long standing is apt to get into a rut; old practices are followed because of conservatism or, perhaps, of the labor involved in adopting more modern and economical ones; "they are not adapted to our conditions, anyway" is often alleged as a reason for not adopting methods characterized as "new-fangled." Old employees gradually shuffle off much of their work on to younger men, retaining jobs that become sinecures. It would be amazing, were it not well known, to state how often an employee is kept on because of some personal knowledge, supposed to be vital, which he has acquired through long employment. "He is more familiar with that mine than anybody living" is said of more than one foreman, when possibly all of his work is being done by some subordinate.

With the march of science, technical processes are constantly being improved and new ones, cheaper and more efficient than the old, are being constantly devised. The manager frequently has little time for technical reading and certainly very much less for observation of new processes and apparatus in operation at other plants. It is not altogether his fault, therefore, that he is not up with the procession. Further, he is a rare man who can regard all his employees impersonally, so impersonally as to judge coolly, in terms of dollars and cents, the work they are doing and the results they are achieving. Finally, from his situation so close to his operation, he lacks the proper perspective of results. What seems good to him may seem bad to the visiting engineer who brings a fresh and untrammeled mind to the problems.

Digitized by Google

The best insurance to the stockholders, against conditions of this kind, is the technical audit. They can get no such assurance from the balance sheet. They should not allow dividends to lull them into a state of satisfaction with their management, nor should they regard the failure of dividends as proof of its incompetence. A technical audit need not be performed every year, perhaps, but it should be a feature of the annual report every two or three years, at least such portions of it as can be given publicity without the risk of harm to the business.

Naturally, the value of a technical audit depends on the selection of the ablest engineer available. It may be said that such service costs money, as indeed it does, but the cost is trivial compared with the profit to be derived. An engineer for such service must have had the broadest experience in all the branches of the industry involved. He should not be a specialist on some particular section of the operation, as such an one might, by some change, uncoördinated with the whole operation, affect the total result adversely. The examining engineer must view the operation as a whole and see that all departments are coördinated, to the end that improvement in one may appear as an improvement in the total and not be at the expense of efficiency in some other department. Taking up a technical audit in detail, it would consist of:

1. A discussion of the conditions surrounding the enterprise, such as transportation facilities, labor supply, power supply, water supply and other auxiliary external factors;

2. The supply of raw materials, conditions influencing the supply or production, including discussion of methods in use and alternate methods suggested;

3. The plant, its equipment, arrangement, etc., discussion of process, methods of operation and operating results;

4. Costs, involving a discussion of detailed costs and the influence of any suggested improvements;

5. Profits, involving a discussion of future markets, selling methods, etc.;

6. Organization and personnel; being a discussion of the industrial organization and cricitism of employees.

It might seem to the layman that such a report would be denominated a business audit. As a matter of fact, that is what it is, and the man to make it is the engineer, because the engineer is, first and foremost, a business man. Engineering is commercialized science, the application of science for the creation of wealth, and no man who, in applying his knowledge, forgets that such is the object, deserves to be called an engineer.

## A. S. T. M. Methods for Analysis of Lead, Tin, Antimony and Copper Alloys

THE American Engineering Standards Committee has before it, for approval as Tentative American Standard, A. S. T. M. Standard Methods for Chemical Analysis of Lead, Tin, Antimony and Copper (B18–21), submitted in accordance with the special procedure under which important standards in existence prior to 1920 may be approved without going through the regular process followed in new work.

These methods as first recommended to the A. S. T. M. in 1917 were based on methods of analysis in use by manufacturers, analytical chemists and other users of the alloys. In 1920, partial revision was made following suggestions of the U. S. Bureau of Standards, and as a result of coöperative analytical work carried out by members of the committee and other chemists. The methods are in the 1921 volume of the A. S. T. M. Standards. Copies may also be obtained from the American Engineering Standards Committee, 29 West 39th St., New York City. Price 25 cents.

The A. E. S. C. would be glad to learn the extent to which these methods meet the needs of the industry.

## Institute of Economics

THE *New York Times* of April 21 announced the establishment of an Institute of Economics which will undertake to supply to private individuals, business concerns and to Government officials reliable information on all economic questions. To finance the new institution, for which there is said to be no precedent, the Carnegie Corporation of New York has set aside $1,600,000. This is expected to pay the costs of the undertaking for ten years. The home of the institute will be in Washington, D. C.

The institute will maintain a paid staff of expert investigators to gather, collate and distribute, or make available, this information in a manner so scientific that its reliability may be unquestionable. Researches will be conducted into every phase of the economic field, but will be confined to present and past conditions. There will be no attempt to forecast possibilities by any system of indices such as are used by economic publications.

The institute's information will be made available through publications, possibly bulletins and pamphlets, and the work will be developed in coöperation with other economic bodies of recognized standing, and with colleges, universities and other institutions.

The first Board of Trustees includes Dr. Arthur T. Hadley, president emeritus of Yale University; Dr. A. Lawrence Lowell, president of Harvard; Dr. Charles D. Walcott of the Smithsonian Institution; Dr. Edwin A. Alderman, president of the University of Virginia; Dr. David Kinley, president of the University of Illinois; Paul Warburg, former member of the Federal Reserve Board; John Barton Payne, chairman of the Central Committee, American Red Cross; Robert S. Brookings, St. Louis; Charles L. Hutchinson, Chicago; David F. Houston, James J. Storrow, Boston; Bolton Smith, Memphis; Whitefoord R. Cole, Nashville; Samuel Mather, Cleveland, and George Sutherland, Salt Lake City.

# Revision of the Mining Law*

By W. R. INGALLS

Consulting Engineer, New York City

THE bases of the work by the committee whereof I am chairman were (1) the abolition of extralateral rights and (2) the preservation of the maximum of the existing laws. The matter of extralateral rights had been under prolonged discussion among mining men and up to the time when our committee began its work (in 1917) the expression of opinion in every way whereby it could be made known —and those ways were extensive—was only a little short of being unanimous that extralateral rights ought to be abolished. I have not observed important evidence indicating a change of opinion on the subject since 1917.

### Abolition of Discovery Logical

Now, when it be decided that extralateral rights ought to be abolished, there can not be merely a simple change to that effect, but it is found that consequential changes are necessary all the way through the existing laws. Abolition of extralateral rights implies abolition of discovery as a prerequisite to location, for otherwise there would be no legal means for locating claims on the dip of a vein. Quite apart from this consideration, abolition of discovery as a prerequisite to location is supported by other good reasons. Among these are the occurrence of orebodies with no exposure on the surface and which often are hidden at great depth. A prospector who has reason to suspect the occurrence of such an orebody must have legal means for the location of a claim within which to explore, and obviously he may not be able to make any discovery on the surface sufficient to locate and hold legally such a claim under the terms of the law as it stands at present.

As a matter of fact, discovery as a prerequisite to location was abolished by common consent many years ago, not only for the reasons that I have given hereinbefore but also for others. It is highly desirable to revise the mining law in this respect, so that it will conform to the conditions of practice and not require people to perjure themselves in making locations, even if it be for praiseworthy purposes.

Formal abolition of extralateral rights implies, moreover, that there is no longer any need for discrimination between placer and lode claims. Moreover, it implies that there is no need for tunnel locations. All complexities and perplexities under those heads therefore can be eliminated from the existing laws; and all desirable forms of location can be made by one type of claim, applicable to all forms and kinds of mineral deposits, except those (coal, petroleum, salines, etc.) that have previously been reserved by the leasing acts. This simplification is accomplished by H. R. 7736.

Further links in the chain of reasoning are that abolition of extralateral rights implies square claims (which we have already in our placer claims, and to which our people are consequently accustomed). Furthermore, it follows that while discovery may be abolished as a prerequisite to location, the whole spirit of our customs, practice and thought requires that it be preserved as a condition for patenting. Therefore, there must be some means for the certification of discovery in cases where a person has been permitted to make location without discovery and this is especially necessary when discovery be made by drill holes or in any way that can not be subsequently observed by everybody.

There are other features introduced into the proposed bill that are not consequential upon abolition of extralateral rights but which reflect the desire to correct admitted evils. In the first place, the existing laws are scattered through the statutes. Collection of them in one place and codification are desirable. This is going to be done anyway, and it is more to the interest of the mining industry to have it done now by mining men than to have it done later by persons who are not so experienced in the industry, and who may not be so much in sympathy with it. As to details, there is a general feeling that the methods of marking claims should be improved, that the system of recording should be improved, etc.

### New Conditions Requiring New Laws

Finally, there are new conditions that have arisen in the prosecution of the mining industry which the present laws do not fit at all, and as to which difficulties are likely to be intensified in the future. Among these are the need of mining companies operating on a large scale to obtain large areas of ground for works,

* The Committee on Mines and Mining of the House of Representatives held its first hearing on H. R. 7736 in Washington on April 27, 1922, and by invitation W. R. Ingalls, chairman of the committee of consulting engineers of the U. S. Bureau of Mines which drafted the bill, appeared before the congressional committee in order to explain it. Dr. H. Foster Bain, director of the Bureau of Mines, was the first witness. He described the steps that led to the appointment of the committee in the U. S. Bureau of Mines. Mr. Ingalls followed. This is the concluding part of his statement.

Digitized by Google

storage of strippings, tailings, etc.; and legal authority for the holding of ground while prospecting for covered ore deposits, perhaps at great depths. Our existing laws do not contemplate such conditions and make no provisions for them.

Our committee may not have formulated the best ways of meeting all of these contingencies, but its general recommendations ought not to be carelessly dismissed, or be condemned offhand. There are some details in the committee's draft that have excited opposition, as to which the committee itself would say that they are unimportant. There are other stipulations as to times, dimensions, etc., for which the committee would cheerfully accept substitutes, if it were convinced that something better were offered. However, it should be borne in mind that such features were generally the result of compromises among the committee, reflecting differences of opinion in the mining industry.

Sometimes these compromises were important, and at other times unimportant. Among the more important were the size of claims, the areas that might be held by a single locator, the matter of annual assessment work, etc.

### Assessment Work and Size of Claims

As to size of claims, there were two radically different views, reflecting differences of opinion in the preliminary discussion among the mining societies and industrial organizations, which came right up into the committee. The mining men of the Northwest generally wanted a square claim of large area. They were acquainted with the large claims of British Columbia. On the other hand, the mining men of the Southwest wanted square claims of small area. They were acquainted with the *pertinencias* of Mexico. The question crystallized between a 40-acre unit and a 10-acre unit. In this particular case, the committee hit upon a compromise that was rather ingenious, I think, in that it provided for alternative units, either of which may be used by the locator as best meets his needs.

With respect to the question of annual assessment work, a good many mining engineers, expressing their opinion without any considerations of psychology and the customs of the "old prospector," were in favor of the abolition of this feature of the existing laws and the substitution of a cash payment to the Government. Our committee recognized the merit of such a recommendation, but it appreciated also that there would be popular dislike for such a provision. We sought to make a compromise between these two views by providing for the continuance of the annual assessment-work idea just as it has been in the past but providing the alternative that persons desiring to pay cash in lieu of assessment work might do so. This is to give people the means for avoiding the performance of utterly useless work, which is simply an economic waste. Even so, our committee contemplated keeping the equivalent within the mining district to which it was due, arranging only that it should serve a useful purpose, such as road building. The protests that have arisen against these considerate and rational provisions are incomprehensible to me.

Another detail in H. R. 7736, as to which opposition has been expressed, and in this case I think it is rather widespread, is that which prescribes for the location of claims in conformity with the lines of the public-land survey. Our committee started with a disagreement as to this, but in the end was unanimous in favor thereof. This was one of the questions as to which there was yielding in order to arrive at an agreement. In the end our committee considered this to be a desirable improvement in our mining laws, but I am sure that the committee would be very far from considering this provision to be an essential. A modification of this to the effect that anyone might locate a claim without regard to the public-land survey, with the proviso that if he did make a location in conformity therewith he would be relieved from the obligation of making a survey for patenting, would meet with the assent of our committee; or, for that matter, so would the omission of any provision with reference to the public-land surveys. The question is one of relatively minor importance in a broad consideration of the revision of the mining laws.

The report of our committee was made to the director of the Bureau of Mines nearly a year ago. The draft for a bill which accompanied it was introduced as H. R. 7736, under date of July 12, 1921, for the purpose of giving it wide publicity and invoking criticism and suggestion. A considerable number of communications regarding it have been received by Mr. Arentz, by the Bureau of Mines and in other quarters, and in a general way I am familiar with them. A good many of these criticisms have reflected mere misunderstanding of the provisions of the proposed bill. A good many of them have been directed against articles which are provisions, word for word, in the existing laws, which our committee did not see fit to alter, acting in this respect upon one of its fundamental principles, *viz.*, to make the minimum of changes from the existing laws.

### Objections Summarized

Mr. Arentz has summarized the objections coming to his attention under five heads: (1) The abolition of extralateral rights; (2) the abolition of discovery as a prerequisite to location; (3) the alternative of a cash payment in lieu of annual assessment work; (4) the requirement for locations to be in conformity with the public-land survey; and (5) the mill-site (or dump) provision. I have already dwelt upon each of these topics in this memorandum. Questions 1 and 2 are fundamental. Questions 3 and 4 refer to details which are in no wise essential in a revision of the mining laws. Question 5 relates to a subject that is of great

Digitized by Google

importance. This pertains not merely to a change in the existing laws, but is an introduction of new matter. The conditions of mining as they are to be foreseen in the future demand something of this nature. Our committee gave the best prescription that it knew how to do, but will welcome any suggestion for improvement. The theory of the formulation that we made is to facilitate large-scale mining operations and at the same time guard public interests. The terms for the acquisition of large areas of ground that we have provided are so onerous that no one will seek to take advantage of them except for legitimate purposes. It is to be noted, moreover, that they confer nothing but surface rights, the mineral rights in such areas being reserved to the Government.

The only thought of our committee throughout its deliberations, which lasted for nearly four years, was of the general public welfare. There were, indeed, introduced provisions looking forward to large-scale mining, naturally for the reason that mining of the future is likely to be so to an increasing degree and there should be good legal means to provide what is necessary. The "old prospector" is left about where he was. If anything, conditions are made easier for him. He can legally take up ground without having to make a discovery or to perjure himself. He is allowed to go upon land that is classified as "non-mineral land." He has only to be a little more orderly in the matter of monumenting and recording and that is to his own interest, the increased protection that is thus afforded to him being well worth his while. If he makes a location without discovery, and subsequently makes discovery, only then does he have to have it certified. Really this does not concern the "old prospector," who goes out and finds a mineral deposit and locates a claim upon it. If he does that his subsequent procedure is substantially the same as heretofore, and he may continue to hold his claim by doing his annual assessment work just as now.

The position of existing claim holders is in no way altered except in their favor. That is to say, they have all the rights and titles that they now possess, extralateral and otherwise, but in addition thereto the present owner of a claim is given everything comprised within his vertical planes that does not belong to anybody else. In other words, an existing claimholder with a location on the apex of a vein retains the right to follow the extension of the vein beyond his side lines, but if there be found within his vertical planes any other orebody, that also is given to him providing no other person has a legal claim upon it.

The committee owed responsibility to nobody but the Federal Government. It was not bound by any expressions of opinion that had been made, or resolutions that had been passed previously by societies. Its sole duty was to draft a bill providing for a revision of the mining laws that would in its judgment serve best for the mining industry and the national welfare.

## Division of War Minerals Supply

THE U. S. Bureau of Mines has established a Division of War Minerals Supply, to be responsible for matters relating to the supply of strategic minerals involved in war plans of the Government, the maintenance of a proper balance of trade among the mineral industries of the nation, and such related duties as may from time to time be assigned to it. H. S. Mulliken, who has for some time acted as special assistant to the director of the Bureau, has been given charge of the work of this division.

The division will coöperate with the General Staff of the War Department, the United States Geological Survey, and a special committee of the American Institute of Mining and Metallurgical Engineers (Arthur S. Dwight, George Otis Smith, H. Foster Bain, J. Edward Spurr, Pope Yeatman, C. K. Leith) in the proposed study of sources of supply and potential production of certain especially selected war minerals.

The head of the division will serve as chairman of the Committee on Strategic Minerals of the Economic Liaison Committee. He has also been placed in administrative charge of all activities in the production of helium that may devolve on the Bureau of Mines, and will serve as one of the Bureau's representatives on the Army and Navy Helium Board.

## Investigation in Wisconsin Zinc District

SINCE the beginning of the milling to recover zinc, the Wisconsin field has borne an undesirable reputation on account of the marcasite which is associated with the sphalerite. The separation has been difficult. A fairly satisfactory process of magnetic separation for grading up jig concentrates which are contaminated with marcasite has been in operation for some time, but the fines are not amenable to this process and have been wasted.

Laboratory tests made by the Bureau of Mines at the Wisconsin State Mining School, Platteville, Wis. indicate that concentrating tables will recover 90 per cent. of the zinc content in a low-grade concentrate assaying about 20 per cent. zinc, and that this concentrate can be graded up to 62 per cent. in central plants where flotation and gravity concentration are combined. An estimate has been made that this practice would have added about one million dollars annually to the revenue for zinc. In some instances the lead recovered would have been appreciable. Two by-products, marcasite and ground limestone would have been available for sulfuric acid and agricultural purposes, respectively.

**A Bibliography** of literature on sampling, compiled by W. J. Sharwood and M. W. Von Bernewitz, has been issued by the U. S. Bureau of Mines. A copy may be obtained from the Director of the Bureau of Mines, Washington, D. C. Ask for Serial No. 2336.

# Government Action of Interest to Engineers

## Extract from Weekly Bulletin Issued by American Engineering Council

MAY 19, 1922

**Coal Conference.**—On May 18, the Secretary of Commerce presided at a meeting of representatives of the coal operators now producing coal, at which a committee was appointed to carry into effect the following proposals: The establishment of district committees to coördinate distribution; the setting up in Washington of a committee to act as a clearing house for the regional committees; Garfield prices put into effect late in 1917 to be the basis for computing fair prices at the mine. In addition, it is planned to conduct the buying for railroads, public utilities and metallurgical plants through centralized committees. Measures also are to be taken to insure the direct progress of coal between producers and consumers. It is hoped to prevent speculation and the pyramiding of prices.

**Muscle Shoals.**—Before the Senate Agricultural Committee, O. C. Merrill, executive secretary of the Federal Power Commission, gave but scant support to proposals by private interests. The House Military Affairs Committee has asked the Attorney General to pass on the validity of contracts executed by the War Department to the Alabama Power Co. in connection with the dam at Muscle Shoals.

**Tariff.**—Leaders will not estimate when this bill may be expected to become law.

**Commodity Divisions to Expand.**—The success which has attended the operation of the commodity divisions in the Department of Commerce has led Congress to appropriate the money for an expanded program in that work. More money will be available for the more important of the existing divisions and new divisions will be set up after July 1, which include separate units to be devoted to export trade in chemicals. The fuel division will be divided and separate units made of coal and petroleum.

MAY 12, 1922

**Muscle Shoals.**—Senator Norris, chairman of the Senate Committee on Agriculture, which is investigating the offers made for the Government properties at Muscle Shoals, has expressed the positive opinion that no one of the offers should be accepted, but that the Government should handle the project itself. Dr. William McClellan, president of the American Institute of Electrical Engineers, and a member of the Executive Board of the Federated American Engineering Societies, appeared before the Senate Committee and urged that Congress take no action until the whole proposal had been submitted to an engineering board of review. He promised to arrange for the services of a committee, to consist of not less than five engineers having long experience with large projects, to make a report to Congress for the handling of the property along business lines.

**Patent Convention.**—The Patent Convention with Germany was revived when formal notice was given Germany, on May 8, that it is the desire of the United States to continue that agreement. The War Department and the manufacturing chemists oppose the revival of the Treaty, but the evidence presented showed clearly that while there would be certain advantages in allowing the convention to elapse, they would be outweighed greatly by the disadvantages. Chemical interests have proposed a compromise to the Senate Patents Committee.

**Tariff.**—After 20 days of discussion, the Senate adopted the Finance Committee's amendments applying to the first paragraph of the tariff bill which prescribes rates for certain acids and anhydrides. It was pointed out that Germany is receiving more chemicals from the United States than she is exporting and in reply it was said that this condition is temporary and that an exact balance in trade between any two nations is not necessary. In an effort to expedite the passage of this bill, the Senate is being convened an hour earlier in the morning and is holding night sessions.

---

## Froth Flotation of Coal

INVESTIGATIONS conducted by the U. S. Bureau of Mines at the University of Washington, show that there is no reason, technically, why many American coals cannot be successfully cleaned of part of their ash and refuse by froth flotation. The process has already been put into successful commercial practice in England and in other foreign coal fields. Its commercial success in this country must, of course, depend on its cost as compared with the present cost of putting clean coal on the market.

# Outlines of the Mining Industry in the Russian Far East*

By P. P. GOUDKOFF

Professor of Economic Geology, Vladivostok Polytechnic Institute

UNDER the name of the Russian Far East we understand the territory occupied by the Amur, Maritime, Sakhalin and Kamchatka Provinces, the total area of which is about 918,000 square miles. The mining industry took its first step in the Russian Far East in the second half of the 19th century, and until the end of this century was restricted to gold placer mining. In the last years of the 19th century, the extraction of coal and lignite was begun, and in 1910–11 the exploitation of silver-lead-zinc mines.

The conditions of the Far Eastern mining industry during the last few years may be outlined by the following figures:

Annual production of gold mines was about 54,000 lb., valued at $13,000,000. During the period of 1910–15 a considerable increase of placer-gold mining by mechanical processes took place; in 1910, by means of dredging and excavators, 500 lb. of gold were obtained; in 1914, 2740 pounds.

Annual output of coal, lignite and silver-lead-zinc ores was:

| | 1911 | 1920 |
|---|---|---|
| Bituminous and semi-anthracite coal, long tons | 270,000 | 316,000 |
| Lignite, long tons | 66,000 | 205,000 |
| Silver-lead-zinc ores, long tons | 28,400 | 94,500 |

In other branches of mining in the Far East, only the quarrying of building stone and clay may be mentioned, the total yearly output amounting to about $500,000 in value.

The principal gold mines are in the Amur Province, in the systems of the Zeia and Bureia rivers, and in Kamchatka Province, near the town of Okhotsk. The above-mentioned tonnage of coal and lignite was extracted from the mines in the Maritime Province, near Vladivostok. The only silver-lead-zinc mine worked was that of Tetiukhe, near the Tetiukhe Bay, 240 miles northeast of Vladivostok. The ores of this mine were exported to Germany, Belgium, and Japan, partly raw, partly calcined.

The slow development of the mining industry in the Far East has been due mainly to the following causes: entire lack of capital; failure to explore the territory; restraints upon initiative due to the closing of certain regions to private mining enterprises, and to the vacillating policy in regard to the employment of yellow labor, such employment having been at one time allowed, at another prohibited.

On the other hand, easy accessibility to the sea, a well developed system of navigable rivers, abundant and widely distributed forest tracts, and a plentiful supply of cheap labor make possible the exceptionally favorable development of the mining industry in the Far East.

## Possibilities of Various Fields

Although more than 83 per cent. of the territory of the Russian Far East still remains unexplored, there have been recorded within its boundaries 713 deposits of 27 different useful minerals, not counting placer gold. Prospects in the different fields may be summarized as follows:

*Gold Mining.*—The opening of new gold-bearing regions; the improvement of placer mining by the introduction of mechanical devices; the development of quartz mines. The gold placers in the Far East are estimated to contain about 13,320,000 lb., worth $3,700,000,000, and it may be said that of all the countries bordering on the Pacific Ocean, the Russian Far East offers the greatest possibilities for the development of gold mining.

*Coal Mining.*—The coal and lignite resources in the known fields are estimated, in millions of long tons, at

| | Coal | Lignite |
|---|---|---|
| Amur Province | 5 | 400 |
| Maritime Province | 70 | 200 |
| Sakhalin Province | 2000 | 2 |
| Kamchatka Province | Very considerable | Considerable |

Among the known coal fields, those in Sakhalin contain high-grade low-ash long-flame and coking coal. The importance of the great resources already located gives us the right to expect their development hand in hand with an increase of the merchant marine, the inevitable change of the river shipping from wood to mineral fuel, the probable development of the metallurgical industry, and the increasing demand for coal and coke in neighboring countries.

* Presented at the Directors' dinner, A. I. M. E., Engineers' Club, March 24, 1922.

Digitized by Google

*Silver-lead-zinc Mining.*—Broad prospects are opened up in connection with the probable discovery of additional valuable deposits in the region of the Tetiukhe mines, the advantageous geographical location of this region, and the favorable market conditions for these metals; in particular, with the noteworthy demand for silver, lead, and zinc in Russia, and for silver in China.

*Oil.*—Oil seepages are known on the eastern coast of Sakhalin, where a strip of seepages is found to extend 231 miles. The oil-bearing horizons are evidently related to the Upper Tertiary. The quality of the oil is not yet determined, but it is clear that with depth the amount of kerosene fractions increases, reaching as high as 44 per cent. It is very probable that in Sakhalin different kinds of oil will be found, as in Japan. There are also unverified data on the seepages of oil on the western coast of Sakhalin and in the Kamchatka Province.

The development of the mining industry of the Russian Far East is of great importance to the general economic situation in the Pacific. On the one hand, it will make the Far East a large market for foreign machinery, and for various materials necessary for the equipment and supply of mining enterprises; on the other hand, it will permit the Russian Far East to contribute its share to the general prosperity of the Pacific through its exports of lead, zinc, silver, rare metals, Sakhalin coal and oil.

## Broken Backs not Fatal

IN RECENT years, according to a statement by Dr. John M. Griffin, superintendent of the Miners' Hospital at Albia, Iowa, out of 44 cases of broken back among coal miners operated on at the Miners' Hospital, 19 have been enabled to return to productive labor in the mines, due to the proper handling of the cases at the time of injury, by the miners skilled in first-aid methods.

A wonderful improvement in the condition of injured miners brought to the hospital for treatment has been noticeable in recent years, says Doctor Griffin's report. Before first aid was instituted among the miners by the U. S. Bureau of Mines, it was not uncommon to have tetanus follow slight injuries. The men now realize the importance of antisepsis and asepsis and have minimized the cases of infection of all kinds by their first-aid dressing. First aid has also taught the men the importance of immediate care of all eye injuries, which means the saving of many eyes in the course of a year.

In fractures and dislocations, first aid has prevented the further injuring of an already injured man, and has made it possible to save many men who otherwise would have been permanently disabled or would have died.

## Authority on Mineral Wealth of Siberia

PROFESSOR P. P. Goudkoff, author of the article that begins on the preceding page, has made extensive investigations of Siberian mining fields. He is in the United States, working on the problem of the restoration of the mining industry of Siberia and the rational future exploitation of its seemingly inexhaustible mineral wealth.

Professor Goudkoff has made geological investigation of more than 300 copper beds in Akmolinsk Province (Kirghiz Steppes); has participated in the work of investigating the Poklevsky-Kezel gold mines in the Urals; has made geological investigation of the gold mine "God's Gift" in Eniseisk Province and the "6th Berikoulsky Plateau" mine in Tomsk Province. He surveyed the Mariinsky and Berikoulsky gold mines in Tomsk Province, as well as several other large mines and mining districts.

P. P. GOUDKOFF.

By order of the Siberian Government, Professor Goudkoff organized the Siberian Geological Committee and was elected first president of that committee. During the Koltchak Government, he was appointed Minister of Commerce and Industry.

## Briquetting Zinc-bearing Material for Distillation

AS a step in the electrothermic smelting of zinc ores, some large-scale briquetting tests were initiated on roasted ore and on a zinc residue concentrate at the Mississippi Valley Experiment Station of the United States Bureau of Mines. Briquettes made of ore, coke, and pitch were shipped to a smelter at Ft. Smith, Ark., for distillation in a natural-gas fired furnace. Ordinary retort distillation on the residue concentrate (containing 36.0 per cent. Zn., 9.5 per cent. Fe., 21 per cent. Pb, 3.1 per cent. CaO, and 3.2 per cent. S.) results in a low recovery of zinc and rapid destruction of retorts. The distillation of this material in briquette form resulted in 97 per cent. zinc extraction, although only 70 per cent. was recovered on account of cold furnace fronts because of partial firing of the furnace for the experimental work. Retort destruction is practically absent with the briquettes and a larger charge can be handled in retorts when in briquette form.

# Oil and Gas Education*

By ROSWELL H. JOHNSON

Professor of Oil and Gas Production, University of Pittsburgh

A CANVASS of the various institutions known or suspected to be giving courses dealing with petroleum and gas revealed the courses listed in the accompanying table, which includes a summary of the number of class hours, as a whole, of the courses listed. It will be observed that the situation is gratifying. Courses are presented in different institutions in the main geographic sections of the country, so that students have no difficulty in obtaining education in this field.

The committee believes that the courses that are offered in many institutions are so inadequate in amount as to make it unwise for students who have not had additional work to consider themselves trained in this field. We strongly urge the few schools now presenting the most adequate courses to develop these more fully, bringing their work up at least to 300 hours, and let other schools concentrate their energies in other fields.

## Specialization Suggested

Three schools in Texas give work in this field and it seems to the committee that it would be far better if an amicable arrangement could be reached whereby one of these schools would specialize in mechanical petroleum engineering and another in chemical petroleum engineering. In California, specialization is already in effect, the economic aspects receiving special attention at Leland Stanford University and technology at the University of California. We suggest that this differentiation be continued.

We recommend that national differentiation be recognized and furthered as follows:

Mechanical field in University of California.

Chemical in University of Oklahoma.

Economic at Leland Stanford University and University of Pittsburgh.

Oil shale at Colorado School of Mines.

The geological work should be adequately treated in all the schools giving petroleum engineering of any type.

The Mid-Continent Oil & Gas Assn., in order to assist students in the various institutions of Texas who intend to enter the oil business, has instituted a series of lectures by practical oil men at the Agricultural and Mechanical College of Texas and the University of Texas. The Association sends to the College once a month a specialist on a particular line of the oil business, such as the geology of oils, production, pumping, refining, preparation of lubricating oils, etc. The Association also plans to provide employment in the oil fields for students from these institutions, so that they may have a practical insight into the business.

The Committee on Education approves this arrangement and hopes that its benefits may become national by similar undertakings in other fields.

## Liquid-oxygen Explosives

EFFORTS have been made by George S. Rice, chief mining engineer of the Bureau of Mines, to have liquid-oxygen explosives tried out practically in this country, but oxygen-liquefying plants are not made in the United States, which limits the use of these explosives in America. In Germany oxygen-liquefying plants are manufactured in various sizes in complete units of apparatus and containers.

Since the war the only extensive development outside of Germany has been in the Lorraine iron mines, where the Germans installed apparatus, and additional apparatus has been put in by the French. One company in Lorraine is mining its entire annual output of 1,500,000 tons of iron ore by the use of these explosives. This company has developed a cartridge of its own on which it has received patents, and has applied for others. It is claimed that the cartridge is an improvement on the German cartridge. The Germans use, for brisant effects, soot; and for slow heaving effects, wood pulp. Either fuse or electric detonators can be used for igniting the charge. The Germans have now developed a method of placing the electric detonator in the bottom of the hole in a special container and have been able to fire large rounds, it is claimed as high as 28 shots at a time.

## Mexican Chamber of Commerce

THE Mexican Chamber of Commerce of the United States, Inc., has been organized to promote business and economic relations between Mexico and the United States, to spread general information of reciprocal interest, and to foster friendly relations. The Board of Directors has 16 members, citizens either of the United States or of Mexico, among them being Elbert H. Gary; the officers are: Sealtiel L. Alatriste, president; James W. Gerard, vice-president; Jerome S. Hess, vice-president; Russell R. Whitmann, vice-president; J. M. Bejarano, treasurer; Jose Romero, secretary.

The offices are in the Woolworth Building, New York City, and at 45 Bolivar St., Mexico City.

# Technical Committee Reports

THE Institute Committee on Industrial Relations, of which Robert Linton is chairman, held a meeting on Feb. 21, listed as one of the technical sessions of the annual meeting, at which reports of the sub-committees were presented. Following are abstracts of these reports. The Institute can furnish mimeographed copies of the complete reports on Safety, Employment, Illness, Mental Factors, and Cripples in Industry. The supply of the other reports has been exhausted.

A paper by George F. Kunz, which was presented at the same meeting, is printed here in full.

## Education

By Charles R. Hook, Chairman of Sub-committee

FOR years there has been no problem of personnel in the industrial world which has had more attention than foremanship.

In any plant, if production is flowing steadily, with a minimum of friction between the departments, if working conditions are good and the men are contented on their jobs, the chances are that that plant has a well organized and intelligent group of foremen. On the other hand, if there is continuous congestion in the flow of work, friction between departments or men, if the men are discontented with their work, their hours or their pay, the chances are that the trouble can be found in the foremen's group. However, the foremen in any plant are largely just what the management encourages, or permits them to be.

The Sub-Committee on Education therefore urges the members of the Institute to undertake to sell the idea of Better Foremanship to industrial managers by showing that a large part of industrial inefficiency is due to the fact that: Foremen as a rule have not been taught leadership; foremen have not been taught how to teach; management has not made a sufficient effort to inform foremen on the problems of management, nor to make "assistant managers" of foremen. In other words, management has belittled the foreman's job.

What is a foreman? Is he a high-class workman, as in some establishments, or is he a low-grade or an assistant manager as in others? He should not be wholly in either of these classes, but rather, a man with knowledge and grasp of the duties and thoughts of the workmen, able to coördinate and direct their effort, and to hold to the point of view of the management. The poorest foremen are those "who use the monkey wrench too much themselves."

Analysis of leadership shows that it is made up of a large number of characteristics; some inborn, and some acquired. The successful foreman must be selected with a view to his natural qualities of leadership, and with a view to his ability to acquire those other abilities which must be acquired by every successful foreman.

A foreman is generally a man who has come up from the ranks of the worker. He usually understands the point of view of those below him and rarely understands the point of view of those above him. The use and results of his particular efforts in a particular part of a plant and their relation to the whole is perhaps blank in his mind. He should be given this point of view through frequent conferences or get-together meetings of the foremen held under the leadership of the management and not through assisting the manager in his duties. The latter plan, often followed in small plants, inclines the foreman too much toward the upper point of view and away from his own function of directing the men and understanding their point of view.

Few foremen will admit upon first thought that teaching is one of their chief duties, yet one of the essential elements of leadership is the ability to transmit one's ideas to others.

Management, too, has given this matter quite inadequate consideration, and foremen can hardly be expected to have a broader view of their duties than management in this matter. Management must take the lead and make adequate provision whereby foremen may be led and helped to give proper consideration to the teaching phase of their jobs.

Perhaps the one factor in industry today which has most to do with low production, low quality and high turnover is mutual distrust. Full and complete information about what management is, its responsibilities, its problems, and its difficulties, works wonders in removing distrust and suspicion from the working force. The foreman is the intermediary for transmitting this information and the interpretation thereof from the management to the men down the line. Management must first form a vital contact with the foreman to post him, to train him on these facts, and further, management must see that the foreman actually does pass this information down to his men. The problem of industrial unrest and distrust will not be solved generally until the foreman is made conscious that he is a party to the facts of management and responsible for the interpretation of these facts to his men.
